Part I

Higgs Physics

1 The Standard Model Higgs boson

It's very nice to be right sometimes...
it has certainly been a long wait.

Peter Higgs

Write intro here

1.1 Spontaneous symmetry breaking

Before talking about symmetry breaking, we need to discuss the concept of symmetry in physics. Symmetry has an essential role in studying physical systems. It manifests not only as a geometric feature of physical objects but also in the dynamics of physical systems. For example, one can find symmetries in the equation of motion, Lagrangians/Hamiltonians and actions. The magnetisation of materials is a good example of the role that symmetry plays in describing physical behaviour. For instance, **paramagnetic** materials have a positive magnetic susceptibility χ_B due to the random arrangement of their electrons' spins. The paramagnetic material spins arrangement will therefore possess rotational symmetry. The material has no *preferred direction* in space [1]. On the contrary, **ferromagnetic** materials with the electrons' spins aligned in a certain direction, will not have such symmetry as there will be a preferred direction, see Figure 1.1.

In particle physics and quantum field theory, symmetry plays an essential role in the taxonomy and dynamics of elementary particles and their bound states, i.e. hadrons, cf. [2, 3]. There are two types of symmetries considered when studying elementary particles and their quantum fields: external and internal symmetries. The first is the symmetry of the spacetime background. Typically, this is a four-dimensional Poincaré symmetry. However, in some models, higher spacetime dimensions or non-flat geometries are considered. Though there is no current evidence of higher dimensions or indications of non-flat spacetime from colliders and cosmological observations [4]. The second class of symmetries is internal symmetries stemming from the quantum nature of these particles/fields. Because their state is described by a **ray** in complex Hilbert/Fock spaces, internal symmetries are simply symmetries of rotations in these spaces that keep the action variation unchanged. Internal symmetries are usually described in terms of simple or product of simple **Lie groups**, e.g. $SU(N)$ ¹, and particles/fields will be arranged

¹Gauge theories based on finite groups have been investigated in the literature, but their phenomenological significance is yet to be further investigated [5, 6]

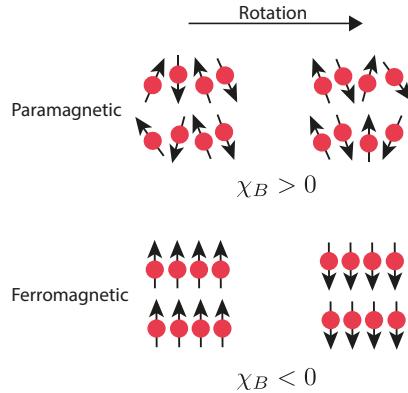

Figure 1.1. In paramagnetic materials, the spins are randomly distributed such that a rotation performed on the system will keep the spin distribution invariant. However, for ferromagnetic materials, where the spins are aligned in a single direction, the symmetry is broken, and the system has a preferred direction.

as multiplets in some representation of the groups. The rotations of the states could be parametrised by constants. In this case, the symmetry is called **global**, or fields of spacetime, where the symmetry is then called **local** or **gauged**.

Gauge symmetries describe rotations in the state space that depend on spacetime, the generator of the gauge transformations could propagate between two spacetime points. This is the way particle/field interactions are described in quantum field theory. The generators of these gauge transformations are called gauge bosons, and they mediate the interactions between the particles/fields and transform under the adjoint representation of the gauge group. Hence, we observe that gauge symmetries are the basis of describing the fundamental interactions of nature, which we call **gauge theories**.

An example of a gauge theory that is realised in nature is the **Standard Model** (SM). Which is a gauge theory based on the group $G_{\text{SM}} := SU(3)_C \otimes SU(2)_L \otimes U(1)_Y$. The first simple group is for the *strong* interaction described by quantum chromodynamics (QCD). The product of the two remaining groups $SU(2)_L \otimes U(1)_Y$ forms the Weinberg-Salam *electroweak* (EW) model [7–9], where $SU(2)_L$ describes the weak interaction which only couples to *left handed* fermions and $U(1)_Y$ is the weak hypercharge Y gauge group, defined by the formula

$$Y = 2(Q - T_3). \quad (1.1)$$

Where Q is the electric charge and T_3 is the third component of the weak isospin. A description of the matter content of the SM and their multiplicities with respect to G_{SM} is shown in [Table 1.1](#)

The SM has been very successful at describing particle interactions even when challenged by numerous precision tests at LEP and SLD [11–14] and later at DØ [15] and the LHC [16, 17]. Nevertheless, it fails to describe the ground state if only the fermion and gauge sectors are considered. The reason for this shortcoming is that the W^\pm and Z bosons have a mass, this violates the EW gauge symmetry. This can be easily seen

Particle/Field	G_{SM} multiplicity	mass [GeV]
Quarks		
$Q = \begin{pmatrix} u_L \\ d_L \end{pmatrix}, \begin{pmatrix} c_L \\ s_L \end{pmatrix}, \begin{pmatrix} t_L \\ b_L \end{pmatrix}$	$(\mathbf{3}, \mathbf{2}, 1/6)$	$m_u = 2.16 \cdot 10^{-3}, m_d = 2.67 \cdot 10^{-3}$
$U = u_R, c_R, t_R$	$(\mathbf{3}, \mathbf{1}, 2/3)$	$m_c = 0.93 \cdot 10^{-2}, m_s = 1.27$
$D = d_R, s_R, b_R$	$(\mathbf{3}, \mathbf{1}, -1/3)$	$m_t = 172.4, m_b = 4.18$
Leptons		
$L = \begin{pmatrix} \nu_{e,L} \\ e_L \end{pmatrix}, \begin{pmatrix} \nu_{\mu,L} \\ \mu_L \end{pmatrix}, \begin{pmatrix} \nu_{\tau,L} \\ \tau_L \end{pmatrix}$	$(\mathbf{1}, \mathbf{2}, -1/2)$	$m_e = 0.511 \cdot 10^{-3}, m_\mu = 1.05 \cdot 10^{-2}$
$E = e_R, \mu_R, \tau_R$	$(\mathbf{1}, \mathbf{1}, -1)$	$m_\tau = 1.77, m_\nu = ??$

Table 1.1. The SM constituents, their multiplicities with respect to the SM gauge group $G_{\text{SM}} := SU(3)_C \otimes SU(2)_L \otimes U(1)_Y$ and masses. The mass of the neutrinos ν is zero according to the SM prediction, but observations suggest that they are massive, and only the difference between the three masses is known [10]. The values of the masses are taken from the Particle Data Group (PDG) [4], and used throughout this thesis.

by looking at the mass term of a spin 1 field B_μ^A

$$\mathcal{L} = m_B B^{A,\mu} B_\mu^A, \quad (1.2)$$

and performing an $SU(N)$ gauge transformation

$$B_\mu^A \rightarrow B_\mu^A + \partial_\mu \Lambda^A + g \varepsilon_{BC}^A B_\mu^B \Lambda^C. \quad (1.3)$$

We see that the mass term is invariant under these transformations. Secondly, because the SM is a chiral theory, as only left-handed fermions would be doublets under $SU(2)_L$, the Dirac mass term

$$\mathcal{L}_D = m_D \bar{\psi}_L \psi_R + \text{h.c.}, \quad (1.4)$$

cannot be a singlet under $SU(2)_L$, hence also violating the EW symmetry. Despite quark and lepton masses being forbidden by the EW symmetry, we indeed observe that they do have a mass, and since they also carry charges this mass has to be a Dirac mass.

In order for the EW model to be consistent at the ground state like it is in the interaction states. A mechanism for spontaneous symmetry breaking going from an interaction state to the vacuum ought to be introduced.

1.1.1 Nambu-Goldstone theorem

Coming back to the example of the paramagnetic-ferromagnetic materials, when heated above a certain temperature, known as the **Curie Temperature** T_C will undergo a phase transition and become paramagnetic (losing their permanent magnet property), in the mean-field theory approximation the magnetic susceptibility is related to the temperature of the metal via the relation

$$\chi_B \sim (T - T_C)^{-\gamma}, \quad (1.5)$$

where γ is a critical exponent. We see that if the metal temperature $T > T_C$ the metal is in an *disordered phase* and when $T < T_C$ it is in the *ordered phase*, i.e. χ_B is the **order parameter** of this system. At the Curie temperature, the system will be at the *critical point* where the susceptibility is divergent. The exponent γ is not used to describe the system at the critical point. There is a “pictorial” description of the metal at the critical point which is helpful in picturing the Goldstone theorem. Starting at $T > T_C$, the metal would be in a paramagnetic phase, where the spins are randomly arranged. As the temperature becomes lower and lower, thermal fluctuations start to lessen. One or more regions of the metal, some of the spins will start to get aligned. With continued cooling, nearing T_C , these turned spins will affect their neighbours turning them into their directions. At the critical point $T = T_C$, the system behaves in a peculiar manner, when one would see regions of spins in “up” and others in “down” directions. The system will resemble a fractal of these regions, becoming scale-invariant. Additionally, waves of oscillating local magnetisation will propagate. These waves, or spinless quasiparticles (called **Magnons**) are Goldstone bosons emerging from spontaneous symmetry breaking.

Which will manifest at $T < T_C$ as the spins will be arranged in a certain single direction and the metal becomes ferromagnetic.

Theorem 1 (Nambu-Goldstone). When a continuous symmetry has a conserved currents but broken in the ground state (vacuum) is called to be spontaneously broken. There is a scalar boson associated with each broken generator of this spontaneously broken symmetry. The modes of these bosons are fluctuations of the order parameter.

This theorem first emerged from condensed matter physics, particularly superconductors [18, 19]. However, it soon got applied to relativistic quantum field theories [20].

1.2 The Higgs mechanism

In order to solve the aforementioned shortcomings of the Weinberg-Salam model, Nambu-Goldstone theorem has been first proposed by P. W. Anderson [21]. However, the way that Anderson formulated his theory was unfamiliar to particle physicists and used a non-relativistic picture to illustrate how photons could gain mass in an electron plasma with a plasma frequency ω_p

$$m_\gamma^{\text{plasma}} = \frac{\hbar\omega_p}{c^2} \quad (1.6)$$

Later on, a theory that explains the mass generation of the EW gauge bosons has been published in an almost simultaneous manner by R. Braut and F. Englert [22], P. Higgs [23] and G. Guralnik, C. R. Hagen, and T. Kibble [24, 25]². The Higgs mechanism starts by considering the spontaneous symmetry breaking (SSB) of the EW sector of the SM via the pattern

$$SU(2)_L \otimes U(1)_Y \longrightarrow U(1)_Q \quad (1.7)$$

This is achieved by the vacuum expectation value (vev) of a complex scalar field $\phi \sim (\mathbf{1}, \mathbf{2}, +1/2)$, with the Lagrangian

$$\mathcal{L} = D_\mu \phi^* D^\mu \phi - V, \quad V := \mu^2 \phi^* \phi + \lambda(\phi^* \phi)^2, \quad (1.8)$$

with V denoting the Higgs potential, illustrated in Figure 1.2, which gives non-vanishing vacuum for $\mu^2 < 0$. The field ϕ is given explicitly by

$$\phi = \begin{pmatrix} \phi^1 + i\phi^2 \\ \frac{1}{\sqrt{2}}(h + v) - i\phi^3 \end{pmatrix} \quad (1.9)$$

The covariant derivative

$$D_\mu = \partial_\mu - ig_2 \frac{\sigma_a}{2} W_\mu^a - ig_1 \frac{1}{2} B_\mu, \quad (1.10)$$

²All of these authors have contributed to the theory of SM spontaneous symmetry breaking (SSB). By calling it the “Higgs” mechanism or boson. I, by no means, have intended to ignore the role played by the rest, rather, I wanted to stick the most widely-used terminology in the field.

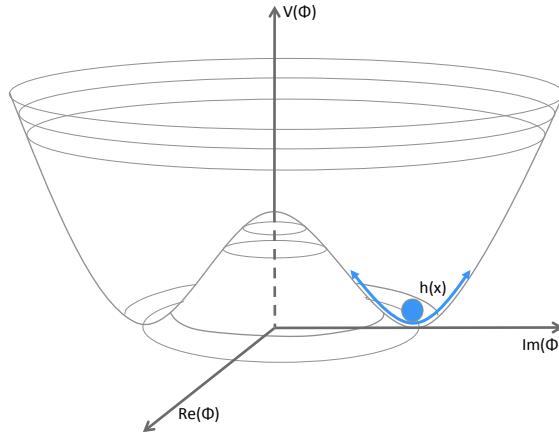

Figure 1.2. The characteristic shape of the Higgs potential showing a non-zero vacuum. While the physical Higgs boson is an oscillation within the energy well illustrated in the diagram with blue arrows., this illustration is taken from [26].

dictates the coupling between the Higgs field and the EW gauge bosons and g_3 , g_2 and g_1 are, respectively, the coupling constants of $SU(3)_C$, $SU(2)_L$ and $U(1)_Y$. The minimum of the scalar potential is then obtained by

$$\frac{\partial V}{\partial \phi} |_{\phi \rightarrow v} = 0, \quad (1.11)$$

which for a tachyonic mass $\mu^2 < 0$ will have a real non-vanishing values v corresponding to the vev of this field $\langle \phi \rangle = (\frac{0}{\sqrt{2}})$.

According to Nambu-Goldstone theorem, the three broken generators of $SU(2)_L \otimes U(1)_Y$ will become massive, and they are the W^\pm and Z bosons, while the photon will remain massless. We will have three massless Goldstone bosons $G^\pm = \frac{1}{2}(\phi^1 \pm i\phi^2)$ and $G^0 = \phi^3$ that are “eaten” by the aforementioned massive photons. Where they become the longitudinal polarisations of W^\pm and Z boson. In order to see this more concretely, we start by looking at the terms of the EW Lagrangian where the field ϕ couples to the gauge bosons, in the unbroken phase

$$D_\mu \phi^* D^\mu \phi = \frac{1}{2} |\partial_\mu \phi|^2 + \frac{1}{8} g_2^2 |\phi|^2 |W_\mu^1 + iW_\mu^2|^2 + \frac{1}{8} |\phi|^2 |g_2 W_\mu^3 - g_1 B_\mu|^2 \quad (1.12)$$

After SSB, we write the gauge bosons in the mass basis

$$\begin{aligned} W_\mu^\pm &= \frac{1}{\sqrt{2}}(W_\mu^1 \pm iW_\mu^2), \\ Z_\mu &= \frac{1}{\sqrt{g_1^2 + g_2^2}} (g_2 W_\mu^3 - g_1 B_\mu), \\ A_\mu &= \frac{1}{\sqrt{g_1^2 + g_2^2}} (g_2 W_\mu^3 + g_1 B_\mu). \end{aligned} \quad (1.13)$$

From this, the electric charge is identified as the coupling constant to the photon A_μ

$$e = \frac{g_1}{\sqrt{g_1^2 + g_2^2}}. \quad (1.14)$$

It is useful to define **Weinberg angle** θ_W , an important EW parameter relating the electric charge to the weak coupling g_2

$$\sin \theta_W = \frac{e}{g_2} \approx 0.231214, \quad (1.15)$$

typically the sin and cos of the Weinberg angle are denoted by s_W and c_W , respectively. We use the unitary gauge, to absorb the Goldstone bosons into the W^\pm and Z longitudinal polarisations. In this gauge the Higgs doublet can be written as

$$\phi \rightarrow \begin{pmatrix} 0 \\ \frac{1}{\sqrt{2}}(h + v) \end{pmatrix}, \quad v = 246 \text{ GeV}. \quad (1.16)$$

With these substitutions, one can read off the masses of the gauge bosons their bilinear terms in (1.12)

$$m_W = \frac{v g_2}{2} \quad m_Z = \frac{v}{2} \sqrt{g_1^2 + g_2^2} \quad m_A = 0. \quad (1.17)$$

Since ϕ is a complex doublet. We have seen that it has four components, and three of them correspond to the Goldstone bosons, thus one remains physical h which is what we now identify with the “Higgs boson” discovered in the Summer of 2012 [27, 28]. The couplings between the Higgs and the electroweak bosons is related to their mass via the vev

$$g_{hVV} = \frac{2m_V^2}{v}, \quad g_{hhVV} = \frac{2m_h^2}{v^2}. \quad (1.18)$$

By substituting (1.16), into the Higgs potential (1.8) one can write the mass of the physical Higgs boson in terms of the vev

$$m_h = \sqrt{2\lambda}v. \quad (1.19)$$

The physical Higgs mass is related to the μ parameter via the relation

$$m_h^2 = -2\mu^2, \quad (1.20)$$

One can see that the mass term after SSB changes its sign, characterising the order-parameter for this system, analogous to the magnetic susceptibility for the magnetisation of materials example. One could also identify the self-couplings of h , the trilinear and quartic couplings

$$g_{hhh} = 3\lambda v = 3\frac{m_h^2}{v}, \quad g_{hhhh} = 3\lambda = 3\frac{m_h^2}{v^2}. \quad (1.21)$$

1.3 Yukawa interaction

It is possible to also use the Higgs vev to give fermions their masses by introducing a Yukawa-interaction terms, first introduced by S. Weinberg [9]

$$\mathcal{L}_{\text{Yuk}} = -y_e \bar{L} \phi E - y_d \bar{Q} \phi D - y_u \bar{Q} \tilde{\phi} U + \text{h.c.}, \quad (1.22)$$

with $\tilde{\phi} = i\sigma_2\phi$ and y_e, y_d, y_u are 3×3 matrices. These matrices are free parameters in the SM. As the Higgs boson acquires a the vev, the fermions will acquire a mass $m_f = vy'_f$ and the Higgs boson coupling to the fermions is given by

$$g_{h\bar{f}f} = \frac{m_f}{v}, \quad (1.23)$$

and the Yukawa matrices will be fixed in the mass basis y'_f by measurements of the fermion masses.

Leptonic Yukawa matrix is diagonal, with a degeneracy between the flavour and masses basis, this manifests as lepton family number conservation (the lepton family operator commutes with the Hamiltonian.). However, for the quarks, the situation is more complicated. One can rotate these matrices to the mass basis via a bi-unitary transformation via the unitary matrices $\mathcal{V}_Q, \mathcal{U}_Q$ for $q = u, d$

$$y_q \longrightarrow y'_f = \mathcal{V}_q^\dagger y_q \mathcal{U}_q = \text{diag}(m_{q_1}, m_{q_2}, m_{q_3}). \quad (1.24)$$

However, there is no degeneracy here as the Hamiltonian does not commute with the quark flavour operator. This is because the transformation matrices for the up and down-type quarks are not the same. The charged EW quark currents contains flavour mixing described by the Cabibbo-Kobayashi-Maskawa (CKM) matrix [29, 30]. More details on the flavour sector of the SM is discussed in ??

Figure 1.3 shows all the SM couplings' strengths, with the thickness of the chord is proportional to the strength of the coupling, one can see the Higgs couplings in orange. In this figure, we cannot easily see Higgs coupling to the fermions, except for its couplings to the third generation. Strictly speaking, if we further examined the Yukawa coupling using a logarithmic scale and focused on the quark sector as Figure 1.4 illustrates. We

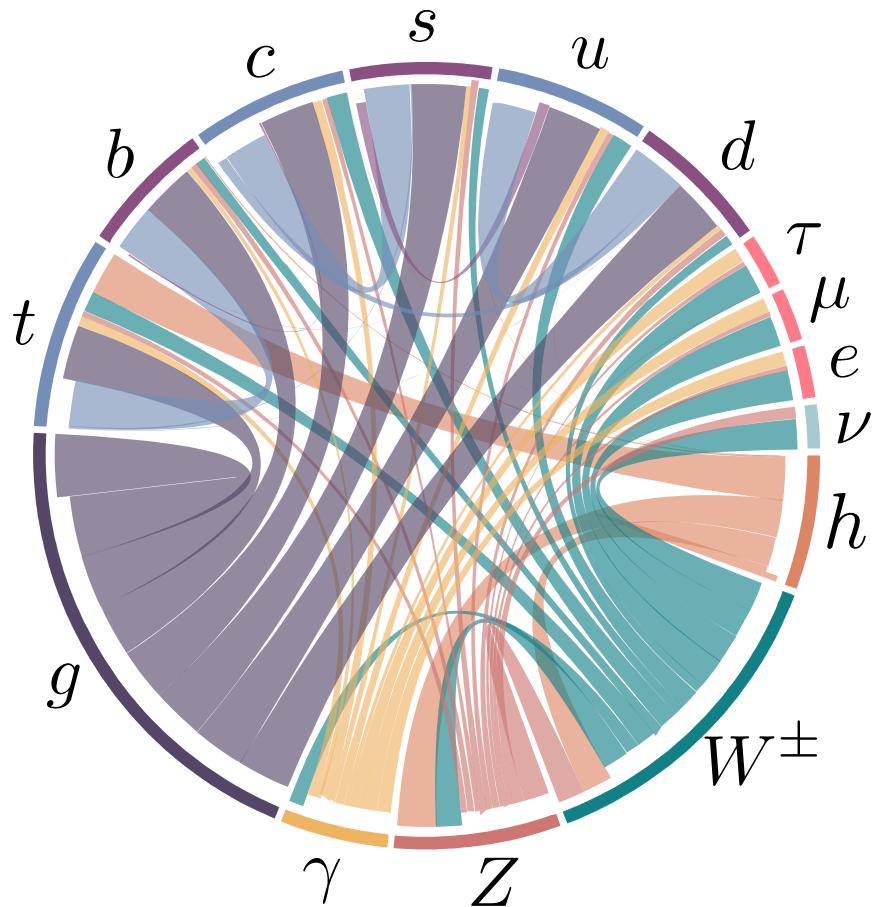

Figure 1.3. The SM Yukawa couplings are proportional to the quark masses, because of the the Higgs Yukawa couplings span about 6 orders of magnitude, as seen in the case of quarks here. This large hierarchy cannot be explained by the SM.

observe that these Yukawa couplings span about 6 orders of magnitudes with marked hierarchy amongst generations. As these couplings are in fact free parameters in the SM, and only determined by the experimental measurements of the quark (or equally applies lepton) masses. This hierarchy of quark masses therefore cannot be explained by the SM Higgs mechanism, and sometimes known as the old flavour puzzle.

In later chapters, we will examine the experimental effort to better measure these couplings and how Higgs pair production can be used to probe them in ???. Even the potential of using techniques from *interpretable machine learning* to further improve Higgs pair sensitivity to probing light Yukawas chapter 6. Then in ?? we'll examine the EFT and UV models to modify them.

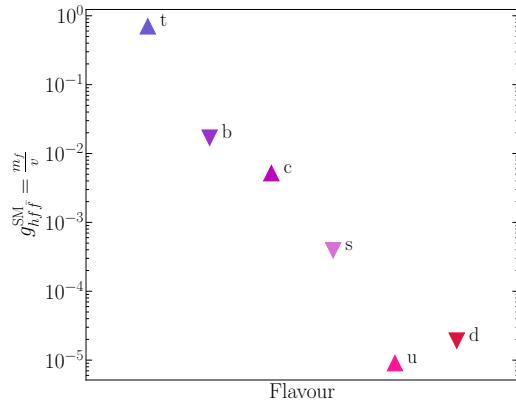

Figure 1.4. A chord diagram showing the SM couplings, with the coupling strength illustrated by the chord thickness. Higgs couplings are coloured in orange.

1.4 The Higgs and EW precision observables

Higgs physics is intertwined with the EW sector for example, the Higgs vev is determined from Fermi's constant $v = (\sqrt{2}G_F)^{-1/2}$, and is fixed by muon lifetime measurements, and comparing it with the theoretical predictions [31–34]

$$\tau_\mu^{-1} = \frac{G_F^2 m_\mu^5}{192\pi^3} \left(1 - \frac{8m_e^2}{m_\mu}\right) \left[1 - 1.810 \frac{\alpha}{\pi} + (6.701 \pm 0.002) \left(\frac{\alpha}{\pi}\right)^2\right], \quad (1.25)$$

which leads to the numerical value of G_F [4]

$$G_F = 1.1663787(6) \cdot 10^{-5} \text{ GeV}^{-2}, \quad (1.26)$$

given the value of the fine structure constant $\alpha^{-1} = 137.03599976(50)$.

Another important EW precision observable (EWPO) is the ratio between the W and

Z masses

$$\rho = \frac{m_W^2}{c_W^2 m_Z^2}. \quad (1.27)$$

At leading order, this parameter is equal to unity in the SM. The ρ parameter depends on the representation of the scalar sector of the EW model having ϕ_i scalars with T_i weak isospin and $T_{3,i}$ being its third component, and a vev v_i , via the relation [35, 36]

$$\rho = \frac{\sum_i [T_i(T_i + 1) - T_{3,i}^2] v_i^2}{2 \sum_i T_{3,i}^2 v_i^2}. \quad (1.28)$$

From (1.28) one can see that a real triplet scalar, for instance, would not fit the experimental EW measurement of ρ . Hence, a complex doublet is the simplest scalar possible for the EW symmetry breaking, and the Higgs boson was expected to be seen almost four decades before its discovery. However, radiative corrections to the EW gauge bosons mass from vacuum polarisation diagrams could potentially cause ρ to deviate significantly from unity. This is not the case, as the experimentally measured value of ρ [4]

$$\rho_{\text{exp}} = 1.00038 \pm 0.00020 \quad (1.29)$$

Additionally, it is possible to think of an extended Higgs sector, where there are multiple scalars with different $SU(2)_L$ multiplicities. Or, a composite Higgs sector, where the Higgs boson is a pseudo Nambu-Goldstone boson, cf. [37, 38]. How can such models be built assuring the ρ parameter is protected from change? The answer to this question lies in a symmetry of the Higgs Lagrangian known as custodial symmetry.

1.4.1 Custodial symmetry

After SSB, a residual global symmetry known as the custodial symmetry protects the ρ parameter from obtaining large radiative corrections at higher orders in perturbation theory. This symmetry must be kept in extended or composite Higgs models. This symmetry can be seen by rewriting the Higgs potential as

$$V = \frac{\lambda}{4} (\phi_1^2 + \phi_2^2 + \phi_3^2 + \phi_4^2 - 2\mu^2)^2. \quad (1.30)$$

This potential is invariant under $SO(4) \simeq SU(2)_L \otimes SU(2)_R$ rotations. However, when the Higgs field squires a non-vanishing vev, $\phi_4 \rightarrow h + v$, the potential becomes

$$V = \frac{\lambda}{4} (\phi_1^2 + \phi_2^2 + \phi_3^2 + h^2 + 2vh + v^2 - 2\mu^2)^2, \quad (1.31)$$

which is only invariant under $SO(3) \simeq SU(2)_V$ transformations, the diagonal part of the original group. This global SSB pattern comes alongside the EW SSB of the gauge group $SU(2)_L \otimes U(1)_Y$ as global $SU(2)_L$ is itself the gauged $SU(2)_L$ group. Additionally the T^3 component of the $SU(2)_R$ global group is the gauged $U(1)_Y$ and the T^3 component of the custodial group $SU(2)_V$ is gauged as well and identified to be the electric charge

operator, i.e. the generator of $U(1)_Q$.

$$\underbrace{SU(2)_R}_{\supset U(1)_Y} \otimes \overbrace{SU(2)_L}^{\text{gauged}} \longrightarrow \underbrace{SU(2)_V}_{\supset U(1)_Q}. \quad (1.32)$$

This pattern indicates that the symmetry is already broken by the gauging of the diagonal part of $SU(2)_R$ (the hypercharge). The custodial symmetry is only *approximate* in the limit of $g_1 \rightarrow 0$, and $\rho = 1$ is a consequence of $g_1 \neq 0$. The symmetry breaking pattern $\mathbf{2} \otimes \mathbf{2} = \mathbf{3} \oplus \mathbf{1}$ also allows us to identify the Goldstone bosons as the custodial triplet and the physical Higgs h as the custodial singlet, explaining the electric charge pattern they have.

We could use the isomorphism between the special orthogonal and special unitary groups to parametrise the Higgs doublet as an $SU(2)_L \otimes SU(2)_R$ bidoublet

$$\mathcal{H} = (\tilde{\phi} \ \phi) = \frac{1}{\sqrt{2}} \begin{pmatrix} \phi_4 - i\phi_3 & \phi_1 + i\phi_2 \\ \phi_1 - i\phi_2 & \phi_4 + i\phi_3 \end{pmatrix}, \quad (1.33)$$

with the bi-unitary transformations

$$\mathcal{H} \longrightarrow \mathcal{U}_L \mathcal{H} \mathcal{U}_R^\dagger \quad (1.34)$$

which leaves any traces of the form $\text{Tr}(\mathcal{H}^\dagger \mathcal{H})$, invariant. The Higgs potential could be rewritten in terms of the bidoublet

$$V = -\frac{\mu^2}{2} \text{Tr}(\mathcal{H}^\dagger \mathcal{H} + \frac{\lambda}{4} (\text{Tr}(\mathcal{H}^\dagger \mathcal{H}))^2) \quad (1.35)$$

The vev is hence written in this representation as

$$\langle \mathcal{H} \rangle = \frac{v}{\sqrt{2}} \mathbb{1}_{2 \times 2}. \quad (1.36)$$

We can also look at the Yukawa sector, and observe that in the case where $y_u = y_d = y$, we can also write the left-handed and right-handed quarks as $SU(2)_L \otimes SU(2)_R$ bidoublets and $SU(2)_R$ doublets, respectively. Hence, the quark part of the Yukawa Lagrangian in (1.22) becomes

$$\mathcal{L}_{yuk} \supset \frac{y}{\sqrt{2}} (\bar{u}_L \ \bar{d}_L) \begin{pmatrix} \phi_4 - i\phi_3 & \phi_1 + i\phi_2 \\ \phi_1 - i\phi_2 & \phi_4 + i\phi_3 \end{pmatrix} \begin{pmatrix} u_R \\ d_R \end{pmatrix}, \quad (1.37)$$

which is invariant under custodial transformations, but when $y_u \neq y_d$, this Lagrangian term breaks custodial symmetry. Thus, the differences between the up-type and down-type quark masses $m_u - m_d$ are considered **spurions** of the custodial symmetry and one expects to see radiative corrections to ρ being proportional to these spurions.

In order to see this more concretely, we start by examining the radiative corrections

that could contribute to the deviation of ρ from unity, i.e. $\Delta\rho$ these corrections are known as the **oblique correction**. These oblique corrections come from electroweak vacuum polarisations $\Pi_{VV}(p^2)$, as shown in Figure 1.5, for more details on these corrections and their calculation see Refs.. [39, 40]

The 1-loop correction to the ρ parameter is given in terms of the Π_{VV} by

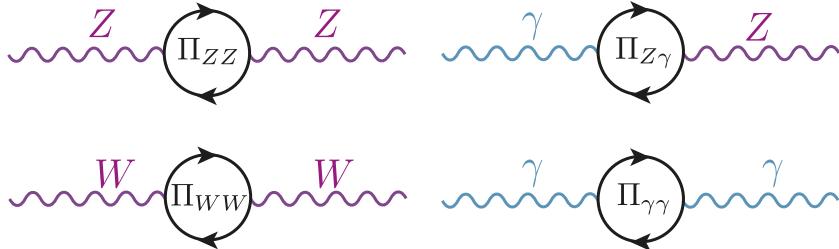

Figure 1.5. The oblique corrections, are radiative correction with electroweak gauge bosons propagators. Namely vacuum polarisations of the Z , W^\pm and γ bosons.

$$\Delta\rho = \frac{\Pi_{WW}(0)}{m_W^2} - \frac{\Pi_{ZZ}(0)}{m_Z^2} \quad (1.38)$$

Where the dominant contributions are given by [41]

$$\Delta\rho = \frac{3G_F}{8\sqrt{2}\pi^2} \left((m_t^2 + m_b^2) - \frac{2m_t^2 m_b^2}{m_t^2 - m_b^2} \ln \frac{m_t^2}{m_b^2} \right) + \dots \quad (1.39)$$

Since $m_b \ll m_t$, the correction is non-vanishing, and (1.39) shows clearly how the radiative corrections are proportional to the spurions of the custodial symmetry. However, this radiative correction is absorbed into the SM definition of ρ , i.e. the $\overline{\text{MS}}$ definition of the ρ -parameter $\rho^{\overline{\text{MS}}}$.

One can study new physics (NP) effects that violates custodial symmetry, by looking at deviations from $\rho = 1$ from it. Given the experimentally measured value of ρ (1.29) many NP models violating custodial symmetry can already be excluded. Nevertheless, ρ alone does not capture the full story of EWPO's. For instance, adding a new quark doublet would not necessarily violate the custodial symmetry though it still can be excluded by EWPO. It is hence useful to introduce new parameters known as **the oblique parameters** [40, 42–45] ³

³The are also called the Peskin–Takeuchi parameters, however, W. Marciano and J. Rosner also D. Kennedy and P. Langacker published the same parametrisation proposals almost simultaneously. Therefore, I preferred not to use this eponym, instead calling them the oblique parameters, as they stem from the oblique corrections .

The oblique parameters

$$\begin{aligned}
 S &:= \frac{4c_W^2 s_W^2}{\alpha} \left[\frac{\Pi_{ZZ}^{\text{NP}}(m_Z^2) - \Pi_{ZZ}^{\text{NP}}(0)}{m_Z^2} - \frac{c_W^2 - s_W^2}{c_W s_W} \frac{\Pi_{Z\gamma}^{\text{NP}}(m_Z^2)}{m_Z^2} - \frac{\Pi_{\gamma\gamma}^{\text{NP}}(m_Z^2)}{m_Z^2} \right], \\
 T &:= \frac{\rho^{\overline{\text{MS}}} - 1}{\alpha} = \frac{1}{\alpha} \left[\frac{\Pi_{WW}^{\text{NP}}(0)}{m_W^2} - \frac{\Pi_{ZZ}^{\text{NP}}(0)}{m_Z^2} \right], \\
 U &:= \frac{4s_W^2}{\alpha} \left[\frac{\Pi_{WW}^{\text{NP}}(m_W^2) - \Pi_{WW}^{\text{NP}}(0)}{m_W^2} - \frac{c_W}{s_W} \frac{\Pi_{Z\gamma}^{\text{NP}}(m_Z^2)}{m_Z^2} - \frac{\Pi_{\gamma\gamma}^{\text{NP}}(m_Z^2)}{m_Z^2} \right] - S.
 \end{aligned} \tag{1.40}$$

The NP contributions to the EW vacuum polarisations $\Pi_{VV}^{\text{NP}}(p^2)$ could either come from loop or tree-level effects. Typically both T and U are related to custodial symmetry violation. However, U has an extra suppression factor of m_{NP}^2/m_Z^2 compared to T and S . The most recent fit result for these parameters is [4]

$$\begin{aligned}
 S &= -0.01 \pm 0.10, \\
 T &= 0.03 \pm 0.13, \\
 U &:= 0.02 \pm 0.11.
 \end{aligned} \tag{1.41}$$

But since T and S tend to give stronger constraint on NP, due to the suppression factor of U . One can perform a two-parameter fit of S and T setting $U = 0$, thus shown in Figure 1.6, with the numerical values [4],

$$\begin{aligned}
 S &= 0.00 \pm 0.07, \\
 T &= 0.05 \pm 0.06.
 \end{aligned} \tag{1.42}$$

The Peskin-Takeuchi parameters are important in constraining effective operators in the Higgs sector , namely

$$\begin{aligned}
 \hat{O}_S &= \phi^\dagger \sigma_i \phi W_{\mu\nu}^i B^{\mu\nu}, \\
 \hat{O}_T &= |\phi^\dagger D_\mu \phi|^2.
 \end{aligned} \tag{1.43}$$

For example, \hat{O}_S appears in Technicolour models causing large deviations of S compared to its measured value [43, 46–48]. Moreover, The constraints on T parameter is important for top mass generation ans well as modifications to $Zb\bar{b}$ coupling in such models [49, 50]. We will revisit the \hat{O}_T when we discuss the Higgs and effective field theories in chapter 3

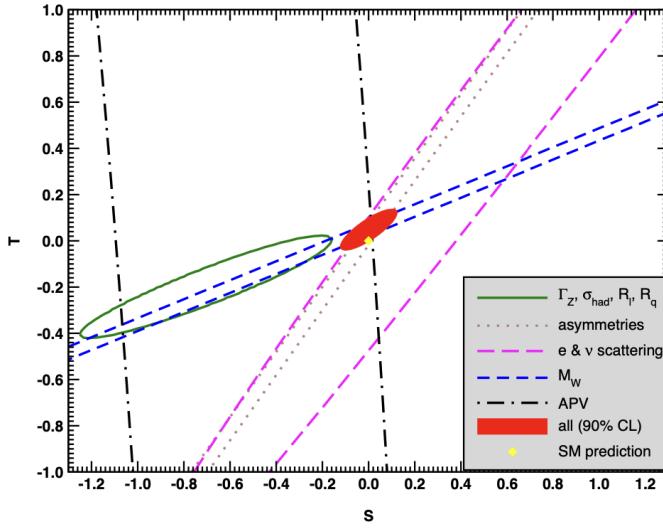

Figure 1.6. Fit results from various EWPO's for T and S setting $U = .$ The contours show 1σ contours (39.35% for closed contours and 68% for the rest). This plot is obtained from the PDG [4]

1.5 Theoretical constraints on the Higgs

1.5.1 Electroweak precision data fits

Even prior to the discovery of the Higgs boson at LHC in 2012, many theoretical aspects of the Higgs sector provided marked bounds on the Higgs properties, particularly its mass. For instance, using the EWPO measurements at LEP provided an input for a fit based of radiative effects coming from the Higgs boson to such observables [11] as in diagram (a) of Figure 1.8, the bounds improved with the improvements of EWPO measurements, these bounds were known as the “blue band” plots seen with their progression in Figure 1.7.

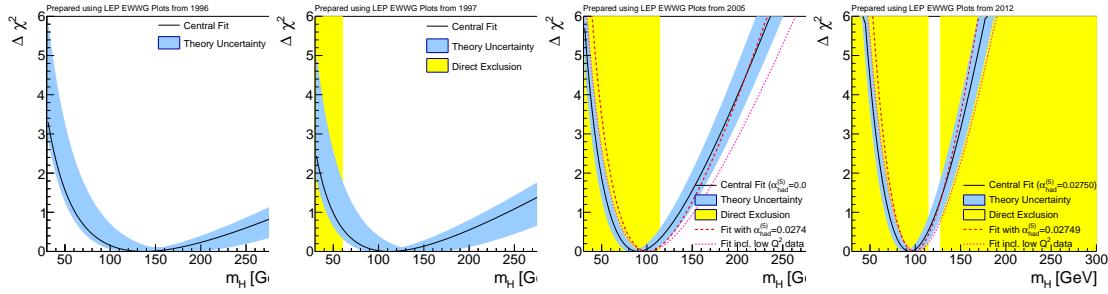

Figure 1.7. Progression of the “blue band” plots with LEP data from 1996 up to 2021 prior to the announcement of the Higgs boson discovery. These plots were taken from [26], based on data from LEP [11]

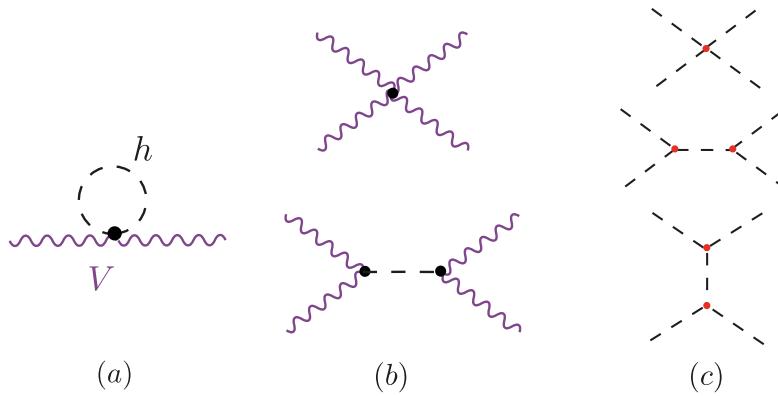

Figure 1.8. Diagrams contributing to theoretical bounds on the Higgs, (a) shows an example of radiative corrections to EWPO from the Higgs bosons. The diagrams in (b) show an elastic scattering of EW vector bosons leading to a bound on the Higgs mass from perturbative unitarity, similarly in (c) diagrams for $hh \rightarrow hh$ scattering leading to constraints on Higgs self-coupling.

1.5.2 Partial-wave unitarity

Another bound on Higgs mass emerged from studying the amplitudes of EW vector bosons elastic scattering having longitudinal polarisations $V_L V_L \rightarrow V_L V_L$ at high energies $E \gg m_W$ (see diagrams (b) in Figure 1.8), where the Goldstone equivalence theorem holds [51]. This bound comes from applying the partial wave perturbative unitarity on the EW boson scattering amplitude. I will derive here this bound starting from the **Optical theorem**, which a direct result from the unitarity of the **S** matrix.

The optical theorem

Let \mathcal{M}_{aa} be a covariant matrix element for an elastic scattering process with for a particle a then the following relation applies

$$\sum_f \int d\Phi_n(p_a, p_i^f) |\mathcal{M}_{af}|^2 = 2\Im(\mathcal{M}_{aa}), \quad (1.44)$$

where the sum is over all intermediate states n -particle states f with momenta p_i^f and $d\Phi_n(p_a, p_i^f)$ is the n -particle phase space.

If we only consider a $2 \rightarrow 2$ process with momentum states. $|p_1, p_2\rangle \rightarrow |k_1, k_2\rangle$, then (1.44), after expanding the 2-particle phase space , simplifies to

$$\begin{aligned} & \int \frac{d^3 k_1}{(2\pi)^3 2E_1} \int \frac{d^3 k_2}{(2\pi)^3 2E_2} (2\pi)^4 \delta^4(p_1 + p_2 - k_1 - k_2) |\mathcal{M}(s, t)|^2, \\ &= \frac{1}{16\pi} \int_{-1}^1 d(\cos \theta) |\mathcal{M}(s, t)|^2, \end{aligned} \quad (1.45)$$

with the Mandelstam variables

$$\begin{aligned} s &= k_1 + k_2, \\ t &= k_1 - p_1, \\ u &= k_1 - p_2, \\ s + t + u &= 4m \end{aligned} \tag{1.46}$$

Recall that the relation between the Mandelstam variable t , and the scattering angle for the elastic scattering is given by

$$t = \frac{1}{2}(s - 4m^2)(\cos \theta - 1) \tag{1.47}$$

We could expand the matrix element $\mathcal{M}(s, t)$ in terms of *partial waves*, isolating s from scattering angle dependence

$$\mathcal{M}(s, t) = 16\pi \sum_j (2j + 1) a_j P_j(\cos \theta). \tag{1.48}$$

Where a_j are called the j th partial wave amplitude, and $P_j(\cos \theta)$ are the Legendre polynomials

$$P_j(z) = \frac{1}{j!} \frac{1}{2^j} \frac{d^j}{dz^j} (z^2 - 1)^j \tag{1.49}$$

Which satisfies the orthonormality condition

$$\int_{-1}^1 dz P_j(z) P_k(z) = \frac{1}{2j + 1} \delta_{jk} \tag{1.50a}$$

$$P_j(1) = 1 \quad \forall j. \tag{1.50b}$$

We hence get for the LHS of (1.44) scattering

$$\begin{aligned} &\int \frac{d^3 k_1}{(2\pi)^3 2E_1} \int \frac{d^3 k_2}{(2\pi)^3 2E_2} (2\pi)^4 \delta^4(p_1 + p_2 - k_1 - k_2) |\mathcal{M}(s, t)|^2, \\ &= \frac{1}{16\pi} \int_{-1}^1 d(\cos \theta) \left[16\pi \sum_j (2j + 1) a_j(s) P_j(\cos \theta) \right] \times \\ &\quad \left[16\pi \sum_k (2k + 1) a_k^*(s) P_k(\cos \theta) \right], \\ &\Rightarrow = 32\pi \sum_j (2j + 1) |a_j(s)|^2. \end{aligned} \tag{1.51}$$

And the RHS of (1.44)

$$2\Im(\mathcal{M}_{aa}) = \underbrace{2\Im(\mathcal{M}(s, 0))}_{t \text{ is integrated out.}} = 32\pi \sum_j (2j+1)\Im(a_j(s)). \quad (1.52)$$

Otherwise large cancellations needed, $a_j(s)$'s are hierachal. Thus, we could compare the partial wave amplitudes term-by-term

$$|a_j(s)|^2 \leq \Im(a_j(s)) \Rightarrow \Re(a_j(s))^2 + \Im(a_j(s))^2 \leq \Im(a_j(s)) \quad (1.53)$$

Rearranging terms, we get

$$\Re(a_j(s)) + \left(\Im(a_j(s)) - \frac{1}{2} \right)^2 \leq \frac{1}{4} \quad (1.54)$$

The partial wave amplitude has to lie within the unitarity circle. We use though perturbation theory if the partial wave amplitude respects the inequality

$$\Re(a_j(s)) \leq \frac{1}{2} \quad (1.55)$$

This is known as the perturbative partial wave unitarity bound.

When (1.55) is applied for $V_L V_L \rightarrow V_L V_L$, in the Goldstone boson equivalence theorem regime in particular for $V = W$ boson, we get for the S -wave partial amplitude

$$a_0 \sim \frac{m_h^2}{16\pi v^2} \left(2 + \mathcal{O}\left(m_h^2/s\right) \right). \quad (1.56)$$

Looking at the asymptotic behaviour as $s \rightarrow \infty$, we obtain the bound

$$\frac{m_h^2}{8\pi v^2} < \frac{1}{2} \Leftrightarrow m_h \leq 870 \text{ GeV}. \quad (1.57)$$

Indeed this bound is obsolete now after th Higgs mass measurement, however it is very important to demonstrate the power of this technique in constraining Higgs parameters. As this method can be applied to any elastic scattering with the Higgs acts as a mediator like $ZZ \rightarrow ZZ$, $WW \rightarrow ff$ and constrain the corresponding couplings g_{ZZh} , g_{ffh} and so on. An important bound can be derived by examining the Higgs elastic scattering $hh \rightarrow hh$ shown in (c) of Figure 1.8 in order to set bounds on Higgs self-interactions g_{hhh} and g_{hhhh} . This is what exactly has been done in ref. [52] where they have found that the S -wave partial amplitude for this process is given by

$$a_0 = -\frac{1}{2} \frac{\sqrt{s(s-4m_h^2)}}{16\pi s} \left[g_{hhh}^2 \left(\frac{1}{s-m_h^2} - 2 \frac{\log \frac{s-3m_h^2}{m_h^2}}{s-4m_h^2} \right) + g_{hhhh} \right], \quad (1.58)$$

which leads to unitarity bounds on the trilinear g_{hhh} and the quartic g_{hhhh} couplings

$$\left| g_{hhh}/g_{hhh}^{\text{SM}} \right| \lesssim 6.5 \quad \text{and} \quad \left| g_{hhhh}/g_{hhhh}^{\text{SM}} \right| \lesssim 65. \quad (1.59)$$

A stronger constrained can be obtained by looking at the one-loop correction to the $hh \rightarrow hh$ scattering amplitude, within the full kinematic range. The unitarity bound here is obtained by looking at the one-loop amplitude at the threshold, and is given by

$$\left| g_{hhhh}/g_{hhhh}^{\text{SM}} \right| \lesssim 6. \quad (1.60)$$

It should be noted that the unitarity bounds on κ_λ depends on the ansatz use estimating the size the New Physics contributions to the scattering amplitudes. These bounds are, hitherto, the strongest on these two couplings even when compared to the ones coming from current experimental searches.

1.5.3 Other bounds

Further theoretical bounds could be obtained by studying quantum effects on the Higgs potential. For example, if we looked at the solution of the renormalisation group equation (RGE) for the Higgs self-coupling λ with the boundary condition $\lambda(v) = \lambda_0$ and ignoring other SM particle-contributions

$$\lambda(Q^2) = \frac{\lambda_0}{1 - \frac{3}{4\pi^2} \log \frac{Q^2}{v^2}} \quad (1.61)$$

We see that the running of λ will hit a pole, known as **Landau pole** when the denominator vanishes. This will happen at the scale

$$Q_c = v e^{4\pi^2/3\lambda_0} = v e^{4\pi^2 v^2 / 3m_h^2} \quad (1.62)$$

This indicates that the theory will break down at scales larger or equal to Q_c . Since the “critical scale” is a function of the Higgs mass, this allows us to set an upper limit on the Higgs mass assuming the SM will be valid up to a certain scale Q_c . This bound is known as **quantum triviality** bound [53]. This is because the low energy behaviour of (1.61) leads to a vanishing interaction, and if we want the Higgs Lagrangian to be perturbative for all scales, then λ has to be vanishing and the theory becomes non-interacting or *trivial*.

Another bound coming from the RGE of λ is the **stability bound**, which considers the stability of the Higgs potential given the running of λ by requiring that the Higgs potential is an operator bounded from below. This bound is obtained by approximating the solution of the RGE at small λ

$$\lambda(Q^2) \sim \lambda_0 + \frac{1}{16\pi^2} \left[-\frac{12m_t^4}{v^4} + \frac{3}{16} (2g_2^4 + (g_2^2 + g_1^2)^2) \right] \log \frac{Q^2}{v^2} \quad (1.63)$$

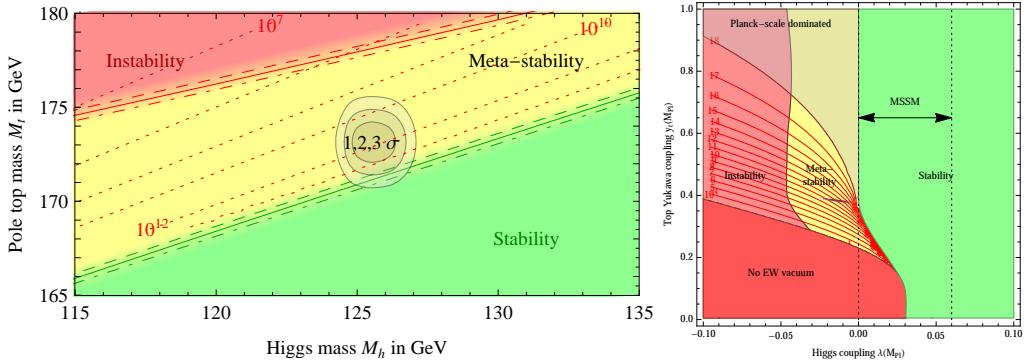

Figure 1.9. Phase diagrams of the Higgs vacuum in the $m_t - m_h$ (left) and $m_t - \lambda(M_{pl})$ (right) planes showing areas of instability, meta stability and absolute stability. In the $m_t - \lambda(M_{pl})$ diagram, the allowed range of the Higgs self-coupling λ in the Minimal Supersymmetric SM (MSSM), this plot is taken from [57]

For the Higgs potential to be bounded from below $\lambda(Q^2)$ ought to be $\lambda(Q^2) > 0$. With this relation for λ_0 in terms of the mass, we get a bound on m_h

$$m_h^2 > \frac{v^2}{8\pi^2} \left[-\frac{12m_t^4}{v^4} + \frac{3}{16} (2g_2^4 + (g_2^2 + g_1^2)^2) \right] \log \frac{Q^2}{v^2} \quad (1.64)$$

Which leads to $m_h \approx 130$ GeV if we assume that the SM is valid up to the Grand Unified Theory (GUT) scale of $\sim 10^{16}$ GeV and $m_h \approx 180$ GeV for Q being at the Planck scale $\sim 10^{19}$ GeV.

More sophisticated calculations and discussion for the Higgs potential and vacuum stability has been a subject of great interest in pre and post-Higgs discovery eras cf. [53–56] and the most state-of-the-art calculation for the vacuum stability at NNLO has been performed in ref. [57] where they also included finite temperature effects to construct a phase diagram in the $m_t - m_h$ and $m_t - \lambda(M_{pl})$ planes as shown in Figure 1.9. Indicating that the measured Higgs mass is likely compatible with a metastable vacuum rather than absolute stability. This indicates that there is a finite probability for the Higgs vacuum (false vacuum) to decay into a lower energy state (true vacuum) via quantum tunnelling.

2 Experimental measurements of the Higgs boson

The observation of the Higgs boson, then the extensive measurement of its properties and couplings has been on the top of the LHC programme priorities [58]. In the time this thesis was in the writing, the particle physics community will be celebrating a decade since the Higgs boson's discovery. Looking back 10 years ago, when I have witnessed the discovery of the Higgs boson via news press-conference in summer of 2012, and decided to be a part of this enormous step that humanity has taken, I feel astonished by the progress made in understanding this newly discovered particle!

In this chapter, I will start by an overview of the extraordinary LHC and its experiments in section 2.1. Then, I will review the state-of-the-art status of experimental measurements of the Higgs properties in section 2.2, cross-sections and couplings in section 2.3, and at the end I will discuss the challenges and outlook for the future runs of the LHC section 2.4, of which the rest of this thesis is going to be aimed to address a small part of them.

2.1 Overview of the Large Hadron Collider

The Large Hadron Collider (LHC) is the largest particle accelerator in the CERN accelerators complex, with a circumference of about 26 km, with over 9590 superconducting magnets cooled to 1.9 K. It was built as an upgrade to the Large electron positron collider (LEP) which ended its operation in the year 2000. The LHC contains four main experiments situated at the four beam collision points and detectors, and these experiments are: ATLAS, CMS, LHCb and ALICE, there also smaller experiments such as LHCf, MilliQan, TOTEM and others. For more details about the LHC cf. [59, 60] or see the LHC technical design report [61] for more technical details.

The LHC started operation in September of 2008, with low energy proton beams, then gradually increased to an energy of 3.5 TeV per proton to reach a centre of mass energy \sqrt{s} of 7 TeV, and data-taking period started from 2011. By 2012, its energy has increased to $\sqrt{s} = 8$ TeV and operated at this energy for about a year and half, then stopping in mid 2013 concluding what is known as **Run-I**. In 2015, the **Run-II** started with almost double the energy $\sqrt{s} = 13$ TeV, and lasted for ca. 3 years. As this thesis being written, preparations are being made to get **Run-III** started until 2024. During these runs, heavier nuclei such as ^{207}Pb and ^{131}Xe have been collided either with protons or with themselves [62].

From, 2025 and beyond, the **High-Luminosity LHC** (HL-LHC) era will commence,

see Figure 2.2. Where the LHC will be shutdown for extensive upgrades [63] to potentially increase its energy to $\sqrt{s} = 14$ TeV and higher collision rates hence the term *high luminosity*. Which leads us to an important notion in particle physics phenomenology *integrated luminosity*.

The performance of colliders depends on many factors, but for phenomenological studies, like this thesis, one mainly considers the centre of mass energy \sqrt{s} and the integrated luminosity \mathcal{L} . This is mainly due to the fact that particle colliders experiments are basically “counting experiments”, and all of the bounds on physical observables or model parameters are obtained from the number of signal versus background events, and the number of expected events N_{explic} for a given resonance R and a subsequent decay final state X at any collider experiments is given by

$$N_{explic} = \sigma(pp \rightarrow R) \mathcal{B}(R \rightarrow X) \mathcal{L} \epsilon_{SEL}. \quad (2.1)$$

Here ϵ_{SEL} is the selection efficiency, which depends on many factors like the detector geometry and particle identification performance etc., as well as the signal one searches for, it can be improved by better detected or selection cuts. The production cross-section increases typically with quadratically with \sqrt{s} , hence comes the need for higher energies but this can only achieved by building new colliders from scratch. The integrated luminosity can be increased much more easily, by longer running time of the same collider as it is the time integral of the collider’s luminosity $L(t)$ over its operation time T

$$\mathcal{L} = \int^T L(t). \quad (2.2)$$

Therefore, we see that the integrated luminosity for the LHC experiments will increase over time, when more collisions taking place, as seen in figure Figure 2.1 showing the integrated luminosity for ATLAS and CMS experiments. As the protons travel in the LHC in **bunches**, and as these bunches cross, protons collide at a certain frequency f , when two bunches with N_1 and N_2 protons per bunch, respectively. Each bunch will have an effective cross-section $4\pi\sigma_i$ corresponding to their physical sizes $\sigma \sim 16 \mu\text{m}$, the luminosity is therefore given -approximately- by

$$L = \frac{f N_1 N_2}{4\pi\sigma_1\sigma_2}, \quad (2.3)$$

which is for the LHC averages to about 10^{34} collisions $\text{cm}^{-2} \text{s}^{-1}$ [64, 65].

The total physics-viable pp -collisions integrated luminosity for Run-I was $4.57/\text{fb}$ for 7TeV and $20.3/\text{fb}$ for 8TeV (ATLAS [66]) and $5.55/\text{fb}$ at 7TeV and $21.8/\text{fb}$ at 8TeV (CMS [67]). As for Run-II the integrated luminosity is $139/\text{fb}$ at 13TeV (ATLAS [68]) and $137/\text{fb}$ at 13TeV (CMS [67]). The expected integrated luminosity by the end of Run-III is $300/\text{fb}$ [69] and $3000/\text{fb}$ by the end of the HL-LHC at energy of 14TeV [63].

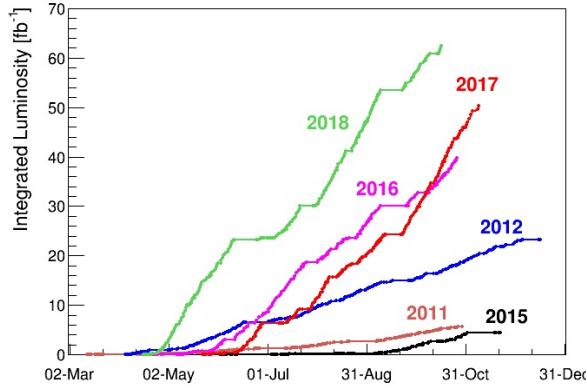

Figure 2.1. The integrated luminosity of the CMS and ATLAS experiments combined over the period from 2011-2018, source [64].

Figure 2.2. A timeline of the LHC operation showing Run-I, Run-II and future planned runs of the LHC, including the HL-LHC, source [62].

2.2 Higgs properties

2.2.1 Higgs boson mass measurements

In order to measure the mass of the Higgs boson with high precision, one needs to consider final states that can be reconstructed with high momentum and mass resolution, this is typically achieved when no hadronic constituents in the decays involved, such as

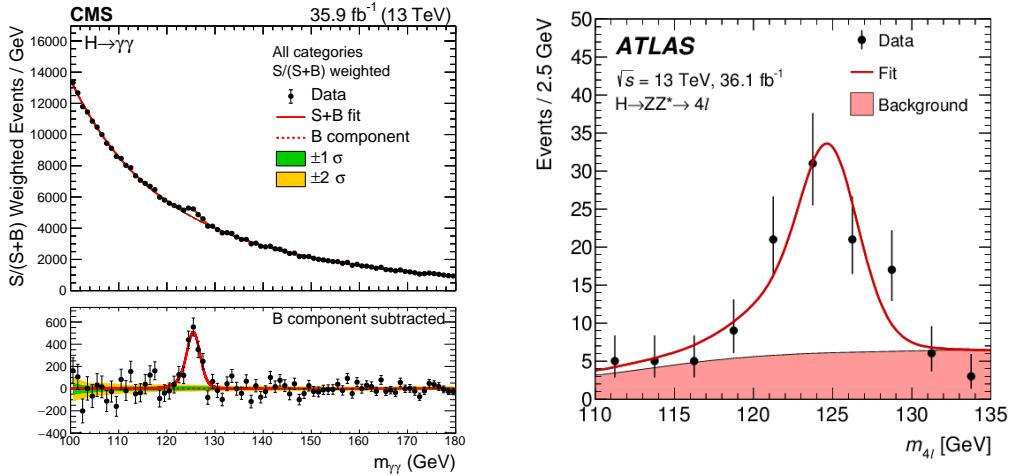

Figure 2.3. The invariant mass distributions of diphoton $m_{\gamma\gamma}$ (CMS [70]) and four lepton $m_{4\ell}$ (ATLAS [71]) final states showing a clear peak at the Higgs mass, with smooth background. These final states are ideal for Higgs mass measurements.

$h \rightarrow \gamma\gamma$ and $h \rightarrow ZZ^* \rightarrow 4\ell$. Reconstructing the invariant mass distributions $m_{\gamma\gamma}$ and $m_{4\ell}$ one observes that the Higgs peak is narrow over a relatively smooth background, see Figure 2.3, which is ideal for the measurement of the Higgs mass. It should be noted that the width of the resonance is due to the detector resolution and does not correspond to the actual Higgs width.

There have been consistent improvements of the Higgs mass measurements since its discovery. In Figure 2.4 I have performed a meta analysis on ATLAS and CMS measurements of the Higgs mass in Run-I and Run-II of the LHC for both diphoton and ZZ^* final states based on the data from the studies [70–73] using a random effects model [74]. The pooling of the studies yielded a mass measurement of $m_h = 125.21 \pm 0.10$, which translates to a 0.11% accuracy, the heterogeneity off the studies was found to be $I^2 = 49\%$ ($p = 0.05$). Different measurements combination techniques were used in [70] and [4] yielded different central values but all of the results agree within the uncertainties.

2.2.2 Higgs full width

The SM values of the Higgs boson full width is $\Gamma_h = 4.1$ GeV and it can be accessed in the LHC by looking at the ratio of on-shell versus off-shell Higgs production and decay to the $ZZ^{(*)}$ state, and $ZZ^{(*)} \rightarrow 4\ell, 2\ell 2\nu$, namely

$$\frac{\sigma(gg \rightarrow h \rightarrow ZZ^*)}{\sigma(gg \rightarrow h^* \rightarrow ZZ)} = \kappa_g^2 \kappa_Z^2 \frac{4m_Z^2}{m_h \Gamma_h}, \quad (2.4)$$

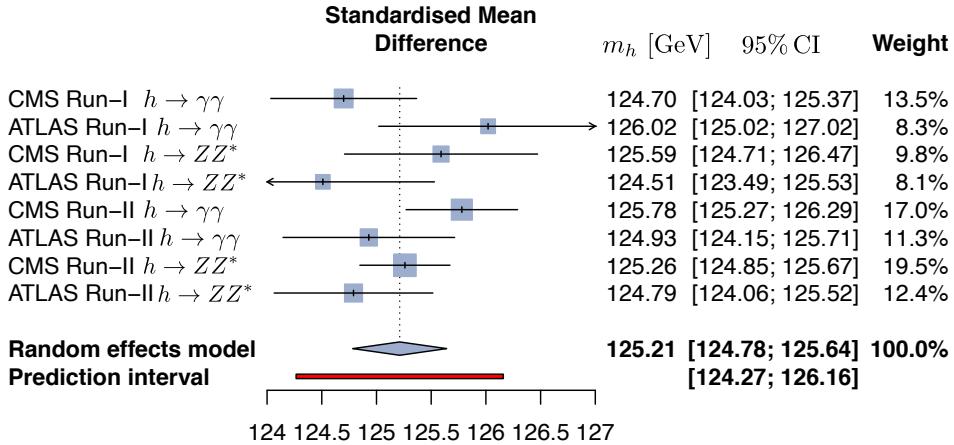

Figure 2.4. A meta analysis preformed to combine all the measurements of the Higgs mass from Run-I and Run-II, the combined result was obtained from pooling all of the studies using the random effects model method.

where the κ here denote the ratio between the measured/ or modified coupling with the Higgs and the SM prediction, i.e.

$$\kappa_X := \frac{g_{XXh}}{g_{X}^{SM}}. \quad (2.5)$$

Which is commonly used in reporting experimental constrains/ measurements of the Higgs couplings, as in the next section [section 2.3](#). We shall discuss the κ formalism more in [chapter 3](#).

We see from (2.4) that if one fixes the coupling between the gluons and the Z boson and the Higgs it is possible to access the full width directly. Unfortunately, it is not possible to directly measure the Higgs full width at the LHC, as this requires full reconstruction of the collision event and study the recoil mass which is only possible at lepton colliders [75, 76]. Alas, it is still possible to extract bounds on Γ_h using (2.4). ATLAS used this method to constrain the full width of the Higgs using Run-II data [77], while CMS has preformed the same analysis using Run-I and Run-II data combined [78], the results are

95% CL bounds of Γ_h

$$\Gamma_h < 14.4 \text{ GeV} \quad (\text{ATLAS}) \qquad 0.08 \text{ GeV} < \Gamma_h < 9.16 \text{ GeV} \quad (\text{CMS}), \quad (2.6)$$

with the combined bound being $\sim 3\Gamma_h^{\text{SM}}$.

2.2.3 Higgs spin and parity

As we have seen in section 1.2, the Higgs boson is a scalar and \mathcal{CP} even ($J^p = 0^+$) in the SM. However, the discovery of a peak in the $m_{\gamma\gamma}$ distribution, would not automatically imply that the particle discovered is scalar, it could be a spin-2 boson, or a pseudoscalar ($J^p = 0^-$). In order to study the J^p properties of the Higgs, one needs to examine the differential distributions of angular variables such as rapidity y or transverse momentum p_T . Both ATLAS and CMS collaborations studied using Run-I data the angular distributions of the Higgs decays $h \rightarrow ZZ^*$, $h \rightarrow WW^*$ and $h \rightarrow \gamma$, to study an anomalous VVh coupling. Then test the alternative hypothesis for J^p against the SM [79, 80]. The analysis results show that the SM 0^+ hypothesis is favoured at $> 99.9\%$ CL.

2.3 Measurements of Higgs rates and couplings

2.3.1 Higgs cross-sections

The total inclusive Higgs cross-section has been measured using the final states $h \rightarrow \gamma\gamma$ and $h \rightarrow ZZ^* \rightarrow 4\ell$, and their combinations. The measurements have been done at the three energies the LHC was operating at: 7 TeV, 8 TeV [81] and 13 TeV [82–84] and combined with more data and compared to the SM prediction as shown in [85]. As shown in Figure 2.5, the measured inclusive cross-section is in agreement with the SM prediction across all of the LHC operation energies.

In addition to the inclusive cross-section measurements, differential cross-sections of the Higgs have been measured for p_T and y as we have seen in subsection 2.2.3 for Higgs's J^p determination. Additionally, the differential cross-sections for other variables have been measured, and they include $N_{\text{jets}}, p_T^{\text{jet}}, m_{jj}, \delta\phi_{jj}$ and others using the channels $h \rightarrow ZZ^*$, $h \rightarrow WW^*$ and $h \rightarrow \gamma$. The most recent results using the full Run-II data can be found in Refs. [83, 85–87].

In addition to the total inclusive cross-section, a collection of measurements of Higgs production and decay rates has been carried out by both ATLAS and CMS. These measurements also carried out in what is known as Standard Template Cross-Sections (STXS) framework. The STXS's are fiducial cross-sections in exclusive phase-space regions or bins separately per Higgs boson production channel. They have the advantage of standardisation of cuts and final results such that measurements could be easily combined across analyses. More details about the STXS framework can be found in the reports of LHC Higgs cross-sections working group (LHCHXSWG) cf. [88]. In Table 2.1 I summarise the state-of-art measurements of the Higgs rates separated into production and decay channels using the total LHC Run-II data from ATLAS and CMS experiments. Additionally,

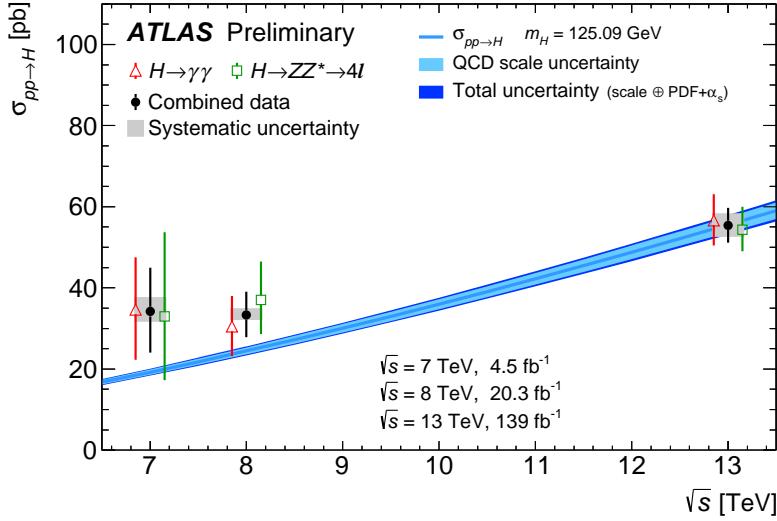

Figure 2.5. The total inclusive cross-section measurements by ATLAS collaboration [85] for 7, 8 and 13 TeV using $h \rightarrow \gamma\gamma$ and $h \rightarrow ZZ^* \rightarrow 4\ell$. channels and their combination (black points) compared to the SM prediction with the uncertainties shown as blue line with light and dark blue bands for QCD scale uncertainties and total uncertainties, respectively.

I give the HL-LHC projections from CMS experiment as a comparison. The results in this table are written in terms of the signal strength, which is directly extracted from measuring the number of events dividing them by the standard model,

$$\mu_{\text{Exp}} := \frac{\sigma \cdot \mathcal{B}}{\sigma^{\text{SM}} \cdot \mathcal{B}^{\text{SM}}} \quad (2.7)$$

2.3.2 Constraints on Higgs couplings

The measurements of the Higgs rates and their combination (also including STXS) have been used to set bounds on the Higgs couplings, the most recent bounds - as this thesis being written - have been reported by ATLAS using the Higgs inclusive rates and STXS for the full Run-II data [94], and by CMS using Higgs rates shown in Table 2.1 [92]. In Figure 2.6, I present the aggregation the ATLAS and CMS bounds on the Higgs coupling modifiers in the κ formalism defined in eq. (2.5). The aggregation of these bounds was preformed using the method described in [95] assuming there is no correlation between ATLAS and CMS measurements.

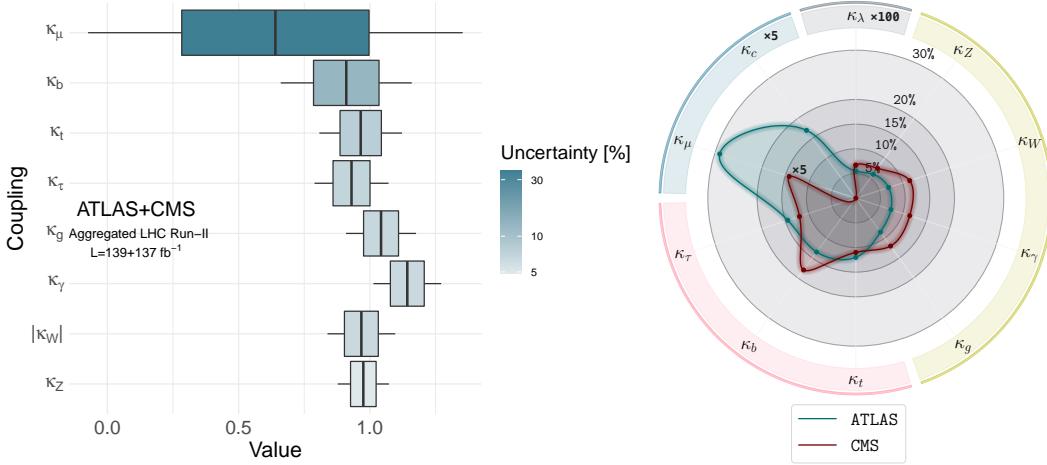

Figure 2.6. Meta analysis aggravating the most recent bounds from ATLAS [94] and CMS [92] on the Higgs coupling modifiers κ . [update the fig](#)

Examining Figure 2.6, we observe that the bounds on the Higgs boson's coupling to the gauge boson, including the effective couplings to γ and g , as well as the couplings to the third-generation fermions are in few percent within the SM prediction. The bounds on the coupling to the W boson seems to favour a negative value in CMS fits, due to the channel used to constraint it $h \rightarrow WW$ which depends on κ_W^2 , thus making the best fit value of ~ -1 within the SM prediction. An independent analysis on the relative signs of κ_W and κ_t was preformed using $th/t\bar{h}$ processes in Ref. [96], hence only the absolute value of κ_W is reported in my combination of the analysis results. Additionally, the observation of the decays $h \rightarrow b\bar{b}$ [97–99] and $h \rightarrow \tau\tau$ [100, 101] leading to direct measurements of the beauty and τ Yukawa couplings has made their bounds comparable to the gauge bosons and top couplings with the Higgs, having less than 10% uncertainty. Au contraire, bounds on the Yukawa couplings of second and first generation fermions remain very weak.

Recently, searches for the decay $h \rightarrow \mu\mu$ [102, 103] using the whole Run-II data by both collaborations, yielded an evidence for its observation of about 3σ . Improving the constraints on κ_μ , though as seen in Figure 2.6, the uncertainty remains high

$\sim 36\%$. Searches for the Higgs decaying to charm pairs is significantly more challenging than the dimuon decays and only yielded an upper 95% CL bounds on $|\kappa_c|$ of 8.5 for ATLAS [104, 105] and 70 for CMS [106]. There is no planned direct searches for the first generation Yukawa couplings (*direct*) measurements planned for the LHC as it is not possible to directly access decays of the Higgs to up or down quarks. Other methods for probing these couplings will be extensively discussed in chapter 6.

By the end of the HL-LHC, it is projected that the couplings of the Higgs, including the couplings with gauge bosons, third generation fermions as well as the muon Yukawa will be measured at few percent level, particularly the couplings with the gauge bosons will be reaching $\sim 1\%$ level uncertainty [107]. This is highlighted by Figure 2.7, this figure shows the improvement in the κ measurement uncertainty expected by the HL-LHC over Run-II.

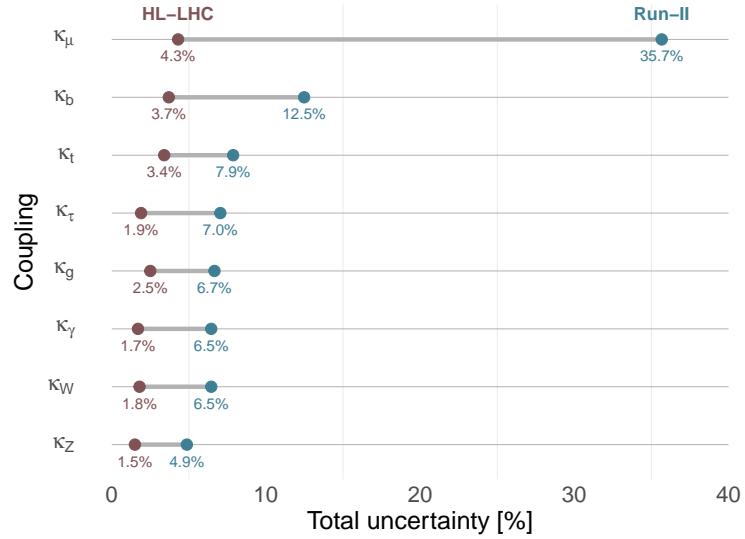

Figure 2.7. Dumbbell plot illustrating the improvement of the uncertainties on the Higgs coupling's measurement project for the HL-LHC compared to the current combined CMS and ATLAS measurements of Run-II.

2.4 Challenges and outlook

The future runs of the LHC hold a lot of potential for further understanding of the 10-year old Higgs boson ! Although, for some processes and couplings there will still be a lot of challenges. For instance, the observation of $h \rightarrow c\bar{c}$ will require highly efficient charm-tagging, which is expected to improve at the HL-LHC by a factor of 2.5 [108]. The signal strength with rare decay $h \rightarrow Z\gamma$ currently is constrained to 3.6 times the SM values at 95% CL [109] and it is projected to be measured at the HL-LHC with $\sim 10\%$ uncertainty.

One of the couplings of the Higgs which we did not discuss above is the Higgs self-interaction (trilinear and quartic), as I have shown in subsection 1.5.2 that the perturbative unitarity bound derived in Ref. [52] is the strongest bound on these couplings so far. This is due to the fact that to experimentally measure the Higgs self-coupling, one needs to search for double Higgs production to access the trilinear self-coupling, and triple Higgs production for the quartic. These processes are very challenging, due to their low inclusive cross-section ~ 30 fb for hh [110] and < 0.1 fb for hhh at LHC maximum expected operational energy of 14 TeV and the latter is challenging even for future colliders of inclusive cross section at 100 TeV of only ~ 5 fb [111]; as opposed to single Higgs production with inclusive cross-section of ~ 70 pb. Certainly the difficulty is aggravated when one considers that the second Higgs would also decay, further lowering the signal strength. The triple Higgs production thus, will not be accessible at the LHC and consequently the quartic self-coupling. However, there is a lot of potential for the trilinear self-coupling, particularly at the HL-LHC.

In ?? I will discuss the potential for using single Higgs processes as proposed by several studies, cf. [112–119] and the challenges accompanying it. Later in chapter 5 the Higgs pair production at the LHC will be overviewed along the current and future searches for this process and the bounds from them on the trilinear Higgs self-coupling.

Another elusive couplings that we have came across are the light Yukawas. In particular light quark Yukawa couplings of the first generation. After overviewing the proposed methods for constraining them, in ?? I will discuss a novel method for directly measuring light quark Yukawa coupling using Higgs pair production. And in chapter 6 a sophisticated method based on interpretable machine learning will be showcased, by which, it is possible to simultaneously constrain the two elusive Higgs interactions: light Yukawas and the trilinear self-coupling using Higgs pair production.

3 Higgs and effective field theories

The study of the Higgs properties, couplings and rates aims to shed light on the structure of its potential, how and why it is responsible for the EW symmetry breaking. Explaining the vacuum expectation value and the mass of the Higgs has been the aim of many theoreticians and phenomenologists. This is because the SM provides no insights on the nature of the Higgs potential and its parameters, as in the SM these are input parameters that is needed to be provided from experimental observations. The Higgs potential shown in eq. (1.8) is the minimal one that could cause the EW symmetry breaking, but nature may not have taken this minimalist approach. In particular, that this potential suffers from severe fine-tuning as we have discussed in the hierarchy problem [add a discussion about this](#).

In order to test whether the Higgs potential and the way it generates SSB is the minimalist SM way or there are other more complex structures involved one needs to measure Higgs rates and compare them with the SM, as overviewed in the previous chapter, using the κ formalism. Alas, this approach does not help in understanding what would the new physics (NP) structures be more likely to case a certain deviation, if any observed. Conversely, we would be interested in knowing what the allowed NP structures given the current (or future) measurements of the Higgs rates are. Of course, by looking at concrete models, one-by-one, confronting them with Higgs data one would get an insight on the aforementioned questions but withal very tedious as there are numerous ways NP might manifest itself.

In order to make our search for NP more accessible and model-agnostic, we could revert to **effective field theories** (EFT), one of the most perspicacious concepts of quantum field theory. In the EFT framework, the interactions mediated by the NP at small scale of an arbitrary complexity can be systematically simplified by approximating these interactions via integrating the UV degrees of freedom thus leaving only numerable operators added to the SM. The premise of EFT's can be simply illustrated in [Figure 3.1](#), the LHC-for example- would not be able to resolve the UV degrees of freedom at their scale Λ , rather one can only observe the effective interactions they mediates. These new effective interactions are parametrised using a set of free parameters known as **Wilson coefficients**, that would be constrained from experiments. These “phenomenological Lagrangians” as called by Weinberg [120], are not necessarily renormalisable but would still allow for robust predictions that can be tested at colliders, including higher order effects . These predictions usually manifest as modifications to rates.

In this chapter I will be discussing the EFT's that modify Higgs rates, including single Higgs and Higgs pair production at leading order. In later chapters like ?? EFT operators from the top quark sector that modify Higgs rates at NLO will be shown. Lastly, in ?? more EFT operators that are responsible for lepton flavour universality

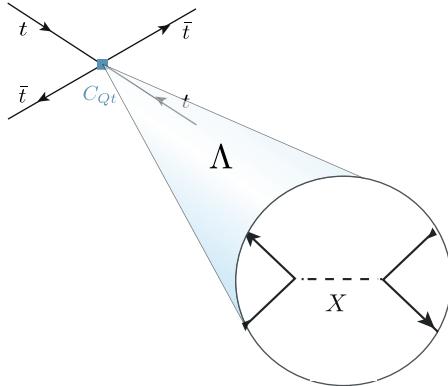

Figure 3.1. eft

violation also at NLO will be showcased. This chapter is organised as follows: In ?? the Higgs sector of Standard Model effective field theory (SMEFT) will be presented along with the parametrisation of single and di-Higgs rates in terms of the SMEFT Wilson coefficients. Au contraire to the SMEFT formalism, section 3.2 will present a non-linear EFT formalism known as the Chiral Lagrangian or (Higgs)EFT . Finally I will conclude this chapter with section 3.3.

3.1 Standard Model EFT

There is no unique way of defining an EFT for the Higgs boson $h(x)$. One could consider the field h as an EW singlet or as a part of the doublet ϕ like the SM. The first ansatz way is more compatible with a heavier Higgs and the effective coupling based on it could be derived from the EW chiral Lagrangian (EWChL) as we shall see in section 3.2. However, after the discovery of the Higgs, having a mass close to m_Z , the second option for an EFT seemed more fitting, though more restrictive. Assuming that the NP resonances would occur at masses $\Lambda \gg m_Z$, one could integrate them out yielding a set of effective operators of mass dimension > 4 . Hence, one can think of the SM Lagrangian of mass dim 2 and 4 as a part of a more general EFT that contain the same fields and symmetries known as the Standard Model Effective field theory (SMEFT).

From simple dimensional analysis, we know that the Higher dimensional operators need to contain an inverse mass with some power $p = 4 - d$ in the couplings, we will have a clear power counting in the SMEFT Lagrangian, such that we could collect all operators of the same mass dimension d into a d -mass-dimensional Lagrangians taking the form

$$\mathcal{L}^{(d)} = \frac{1}{\Lambda^{d-4}} \sum_i C_i \mathcal{O}_i. \quad (3.1)$$

For any $d > 4$ the Lagrangian in eq. (3.1) is not be renormalisable in the strict sense, yet it is still predictive via fitting the Wilson coefficients C_i order-by-order. This power-

counting property allows for predictability even when we, in principle, have infinite number of free Wilson coefficients, as all of these operators are suppressed by the NP scale (irrelevant operators w.r.t. the renormalisation group) [1]. In order to illustrate this, we let $\Lambda = 1$, then the effects of dimension-six operators will be in percent level, while dimension-eight operators will have effects of order $\sim 10^{-4}$, allowing us to ignore the dimension-eight and higher operators. Regarding dimension-five, we have only one operator called the Weinberg operator [121]

$$\mathcal{O}_{\nu\nu} = (\tilde{\phi} L_p)^T \hat{C} (\tilde{\phi}^\dagger L_q), \quad (3.2)$$

where \hat{C} is the charge conjugation operator. The Weinberg operator violates leptonic number and generates neutrino masses after EW symmetry breaking, similar effects are generated from dimension-seven operators [122]. These effects do not yield considerable collider phenomenology. Hence, I shall be discussing SMEFT with dimension-six operators only, for studies on Higher dimensional SMEFT operators cf. [122–125]. The SMEFT Lagrangian up to dimension-six operators is given by

$$\mathcal{L}_{\text{SMEFT}}^{d=6} = \mathcal{L}_{\text{SM}} + \frac{1}{\Lambda^2} \sum_i C_i \mathcal{O}_i. \quad (3.3)$$

The study of dimension-six effective operators in characterising NP effects at energies beyond colliders reach has been first proposed in [127, 128]. Nowadays, phenomenological studies of EFT's with dimension-six operators primarily focus on using a set of complete and non-redundant “basis”. This is due to the fact that different effective operators will correspond to same observables e.g. same scattering amplitudes of SM particles. This is the case if the operators can be related by using equations of motion, Fierz transformations, integration by parts or field redefinitions. This leads to non-trivial and counter-intuitive relations between operators. Thus making the construction of basis for the dimension-six SMEFT Lagrangian of eq. (3.3) a cumbersome task. Such task has been accomplished recently by [126, 129] forming what is known as **Warsaw Basis**. Another set of basis is the strongly-interacting light Higgs basis (SILH), originally proposed by [130], before the Warsaw basis, and completed in [131, 132]. A more recent set of basis has been published in [133] using a subset of couplings characterising the interactions of mass eigenstates in the effective Lagrangian.

The complete $d = 6$ SMEFT is described by 2499 independent parameters [129]. However, if one suppresses the flavour indices, then the dimension-six operators themselves are much less, in the Warsaw basis for example, assuming Baryon number conservation and dropping the flavour indices one has only 59 operators, listed in Table 3.1. It should be noted that all of the basis of SMEFT will produce the same phenomenology, the choice of basis is sometimes helpful in simplifying the analysis. In this thesis, I will mainly focus on Warsaw basis.

The SMEFT operators can either modify SM parameters (couplings, masses) or introduce new vertices that do not exist in the SM, like four-fermion operators, or both like $\mathcal{O}_{\phi e}$. An example of operators modifying SM parameters is $\mathcal{O}_{\phi D}$, which leads to

X^3		Pure Higgs		$\psi^2 \phi^3 + \text{h.c.}$

Table 3.1. Complete list of the dimension-six SMEFT operators in the Warsaw basis [126]. The \mathcal{CP} violating operators contains the dual fields \tilde{X} . The flavour labels of the form p, r, s, t on the \mathcal{O} operators are suppressed on the left hand side of the tables.

modification of the Z boson mass after EW symmetry breaking

$$\frac{C_{\phi D}}{\Lambda^2} |\phi^\dagger D_\mu \phi|^2 \rightarrow \frac{C_{\phi D} v^4}{16\Lambda^2} (g_2^2 + g_1^2) Z^\mu Z_\mu. \quad (3.4)$$

Additionally, from field redefinitions, we get indirect contributions to the W mass from $C_{\phi D}$, combining both effects as a deviation in the ρ parameter, we get

$$\delta\rho = \frac{v^2}{2\Lambda^2} C_{\phi D}. \quad (3.5)$$

Which allows us to constrain $C_{\phi D}$ from the T parameter

$$T = \frac{-2\pi v^2}{\Lambda^2} \frac{(g_1^2 + g_2^2)}{g_1^2 g_2^2} C_{\phi D} \quad (3.6)$$

Another operator that affects the oblique parameters directly is $\mathcal{O}_{\phi WB}$, as it modifies the S parameter in the following way

$$S = \frac{16\pi v^2}{g_1 g_2 \Lambda^2} C_{\phi WB} \quad (3.7)$$

Other SM coupling modifications by SMEFT operators related to EWPO's are investigated in [134], and [?]. Additionally, the contributions of the SMEFT Wilson coefficients to SM parameters are not only from tree-level effects like in eq. (3.4) but could also come at (N)NLO, either from finite or RGE contributions.

SMEFT is suitable as a low energy limit for supersymmetric models [135] or some classes of composite Higgs models [136, 137]

3.1.1 Single Higgs processes in SMEFT

Single Higgs production and decay processes are modified at LO by a relatively long list of operators summarised in eqs. (3.8), (3.9) and (3.10). Explicit formulae for the Higgs rates dependence on the Wilson coefficients of these operators can be found in [138]

SMEFT operators modifying Higgs rates at LO

Higgs operators

$$C_{\phi D}, \mathcal{O}_{\phi\square}, \mathcal{O}_{\phi G}, \mathcal{O}_{\phi W}, \mathcal{O}_{\phi B}, \mathcal{O}_{\phi WB}, \mathcal{O}_{\phi l}^{(1)}, \\ \mathcal{O}_{\phi l}^{(3)}, \mathcal{O}_{\phi e}, \mathcal{O}_{\phi q}^{(1)}, \mathcal{O}_{\phi q}^{(3)}, \mathcal{O}_{\phi u}, \mathcal{O}_{\phi d}, \mathcal{O}_{\tau\phi}, \mathcal{O}_{t\phi}, \mathcal{O}_{b\phi}, \mathcal{O}_{tb\phi}. \quad (3.8)$$

Top-quark operators

$$\mathcal{O}_{tG}, \mathcal{O}_{tW}, \mathcal{O}_{tB}, \quad (3.9)$$

other

$$\mathcal{O}_G, \mathcal{O}_{ll}^{(1)}, \mathcal{O}_{Qq}^{(1),(3)}, \mathcal{O}_{tu}, \mathcal{O}_{td}^{(1),(8)}, \mathcal{O}_{Qu}^{(1),(8)}, \mathcal{O}_{Qd}^{(1),(8)}. \quad (3.10)$$

The third generation quarks are denoted by Q while the first and second generation quarks are assumed to have the same coupling and denoted by q, u, d .

Some of these operators are strongly constrained from EWPO data such as $\mathcal{O}_{\phi D}$ and $\mathcal{O}_{\phi WB}$. Others are weakly constrained from Higgs data alone like the four-fermion or top sector operators, and require additional experimental data to constrain them. Global fits on SMEFT Wilson coefficients can be found in [139]. Where they have used Higgs and EW data on a subset of the SMEFT Wilson coefficients of the operators listed above. The fit also includes RGE and NLO (even NNLO for m_W) effects. While in [140], a global fit for a larger set of operators, but only with LO effects, including EW, Higgs and top data for C_G the fits are found in [141]. More recent study [142] has utilised EWPO data to constrain the four-fermion operators appearing in Higgs rates at LO and others involving four heavy quarks, using their NLO effects to EW bosons pole masses. We shall see in ?? that the four-fermions operators with all heavy quarks will contribute also to Higgs rates at NLO. A wider scope analysis including a wide range of Higgs, top, di-boson and EWPO data has been preformed in [143].

The dependence of single Higgs rates on the SMEFT Wilson coefficients gets more complicated once NLO and higher effects are taken into an account. As shown in the fit results reported from [139], the RGE of these Wilson coefficients introduces new operators that do not appear at LO, also loop corrections to masses of the EW and Higgs bosons as well as their process will depend on some SMEFT coefficients. A prominent example of an operator appearing only at NLO in single Higgs processes is \mathcal{O}_ϕ , which modifies the Higgs self interactions, namely the trilinear coupling.

Typically, in order to probe the Higgs trilinear self-coupling directly, one ought to observe Higgs pair production, see Part II. However, due to the appearance of Higgs self-interaction and its modifiers- C_ϕ in SMEFT context- in (N)NLO EW [144, 145] and Higgs observables [112–119], one can extract bounds on the Higgs trilinear coupling from single Higgs and EWPO data. Figure 3.2 illustrates example Feynman diagrams of single Higgs processes of which the trilinear Higgs self-coupling enters via NLO corrections. Using the results from the aforementioned references, a global fit with all operators that enter at tree-level in addition to the loop effects from the Higgs self-coupling has been

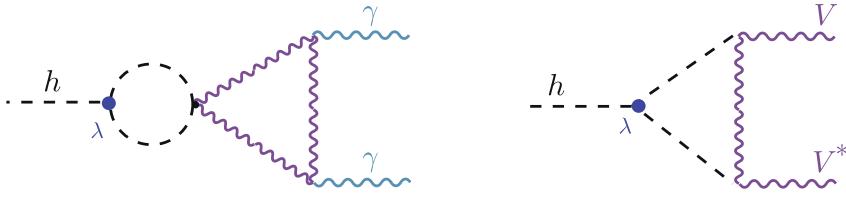

Figure 3.2. NLO EW corrections of single Higgs processes, were the Higgs trilinear self-coupling (the red circle) enters. Here the Higgs decay to two photons is shown as an example.

performed in ref. [146] and later as we have seen in ref. [139]. Additionally, experimental searches for Higgs trilinear self-coupling have been presented by ATLAS [147] and CMS [92].

3.1.2 Higgs pair production and SMEFT

Higgs pair production in Hadron colliders is sensitive to six \mathcal{CP} even SMEFT operators, under the assumption of Minimal Flavour violation (MFV)¹. These operators are

$$\mathcal{O}_{\phi D}, \mathcal{O}_{\phi \square}, \mathcal{O}_\phi, \mathcal{O}_{t\phi}, \mathcal{O}_{\phi G}, \mathcal{O}_{tG}, \quad (3.11)$$

and their effects, with the corresponding colours are illustrated in Figure 3.3, except for $\mathcal{O}_{\phi D}$ and $\mathcal{O}_{\phi \square}$, as they modify all SM Higgs vertices. However, MFV is not the only way to approach SMEFT, there exist more complex flavour structures that allow for significant enhancements of the first and second generation Yukawas with being excluded by flavour observables. Such formalisms will be discussed in ?? and chapter 6, where I discuss the potential for Higgs pair production in probing operators modifying Light Yukawa couplings. Moreover, for Higgs pair production with \mathcal{CP} operators, see ref. [148]. The main operator to constrain from Higgs pair as mentioned before is \mathcal{O}_ϕ , for two reasons; a) the other operators are already strongly constraint from single Higgs and top processes b) the effect of \mathcal{O}_ϕ on Higgs pair production is significantly higher than in single Higgs or EW observables. This is illustrated in Figure 3.4, by comparing the relative change of the gluon fusion cross-sections at NLO QCD for single and di-Higgs production. This is not surprising, since C_ϕ appears at LO in Higgs pair production. Another advantage for Higgs pair production searches is the sensitivity of this process to non-linear couplings, for example diagrams (b) and (d) of Figure 3.3. Although in SMEFT these diagrams correspond to the same operators in (a) and (c), respectively, in an another EFT this is not necessary the case.

¹MFV assumes that new physics operators will follow the same flavour hierarchies as the SM.

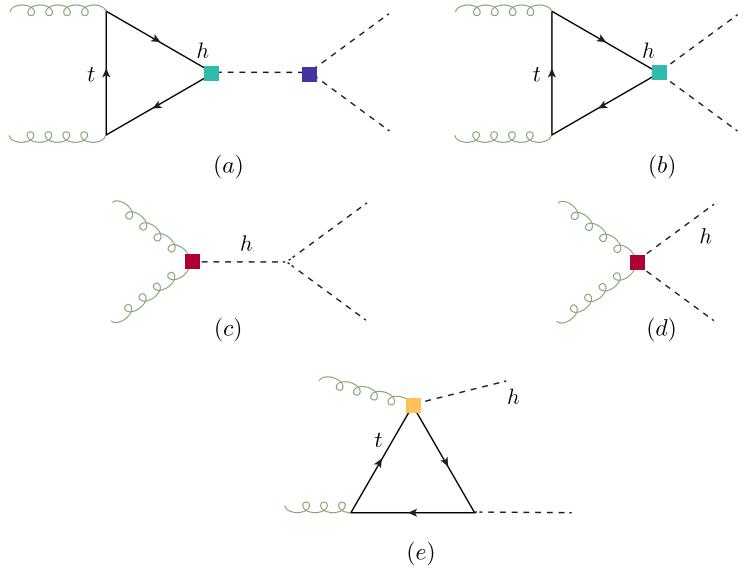

Figure 3.3. Example of diagrams illustrating how the dimension-six SMEFT operators enter in Higgs pair production at Hadron colliders.

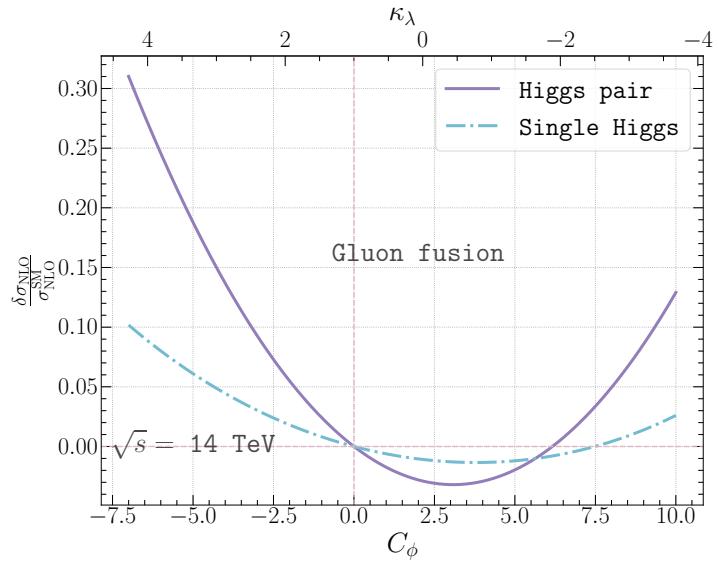

Figure 3.4. The relative change of the NLO QCD cross-section of gluon fusion production of single Higgs (dashed line) and Higgs pair (solid line) at a pp collider with $\sqrt{s} = 14$ TeV as a function of C_ϕ or the corresponding κ_λ .

3.2 The chiral Lagrangian

Given the strong bounds on the ρ parameter, it would plausible to assume that NP would maintain the custodial symmetry $SU(2)_V$, and treat the chiral symmetry breaking pattern $SU(2)_L \otimes SU(2)_R \rightarrow SU(2)_V$ in the same way the QCD chiral symmetry breaking is treated in terms of considering the pions as pNG bosons in order to describe their interaction. For pions this is known as **chiral perturbation theory** [149, 150]. The same mathematical description could be applied for the case of EW symmetry breaking by constructing the EW chiral Lagrangian (EWChL). In the EWChL the Goldstone fields $\pi^a(x)$ of the SM are part of $SU(2)$ unitary transformation

$$\mathcal{U}(x) = e^{i\pi^a(x)\sigma_a/v}, \quad (3.12)$$

which implies that the Goldstone fields transform non-linearly under $SU(2)_L \otimes SU(2)_R$. As for the Higgs field $h(x)$, it is added as an $SU(2)_L \otimes U(1)_Y$ singlet, and appears in the EWChL at any power in principle. As contrary to the power counting in the NP scale Λ like in SMEFT, in the EWChL, one counts the *chiral dimension* χ , defined for the fields as [151, 152]

$$[\phi]_\chi = 0, \quad [X]_\chi = 0, \quad [\partial_\mu]_\chi = 1, \quad [\psi]_\chi = 2. \quad (3.13)$$

The zeroth order term of the EWChL will have $\chi = 2$, higher order terms could be considered as terms generated perturbatively from L loop interactions, with chiral dimensions $\chi = 2L + 2$, hence the first order EWChL or HEFT would have operators of $\chi = 4$. Hence the expansion of the EWChL is in chiral order as well as in powers of $h(x)/v$. This power-counting results in some SMEFT dimension-six operators being considered of higher order in HEFT a prominent example of this is C_{tG} being of chiral dimension 5 in HEFT.

The relevant terms for single and di-Higgs production of the EWChL /HEFT is typically parametrised in the Unitary gauge by [146, 153]

$$\begin{aligned} \mathcal{L}_{\text{HEFT}} = & \frac{h}{v} \left[\left(\delta c_W m_W^2 W_\mu^+ W^{-\mu} + \delta c_Z \frac{m_Z^2}{2} Z_\mu Z^\mu \right) \right. \\ & + c_{ww} \frac{g_2^2}{2} W_{\mu\nu}^+ W^{-\mu\nu} + c_{w\square} g_2^2 \left(W_\mu^- \partial_\nu W^{+\mu\nu} + \text{h.c.} \right) + c_{\gamma\gamma} \frac{\alpha}{8\pi} A_{\mu\nu} A^{\mu\nu} \\ & + c_{zz} \frac{g_2^2 + g_1^2}{4} Z_{\mu\nu} Z^{\mu\nu} + c_{z\gamma} \frac{eg_1}{16\pi^2} Z_{\mu\nu} A^{\mu\nu} + c_{z\square} g_2^2 Z_\mu \partial_\nu Z^{\mu\nu} + c_{\gamma\square} g_2 g_1 Z_\mu \partial_\nu A^{\mu\nu} \Big] \\ & + \frac{\alpha_s}{8\pi} \left(c_{gg} \frac{h}{v} + c_{gg}^{(2)} \frac{h^2}{2v^2} \right) \text{Tr} [G_{\mu\nu} G^{\mu\nu}] - \sum_f \left[m_f \left(c_f \frac{h}{v} + c_{ff} \frac{h^2}{2v^2} \right) \bar{f}_R f_L + \text{h.c.} \right] \\ & - c_{hh} \frac{m_h^2}{2v} h^3 + \dots, \end{aligned} \quad (3.14)$$

I have omitted here the kinetic and mass terms of the Higgs, \mathcal{CP} violating terms, as well as couplings not contributing to the LHC phenomenology and Higher chiral order operators. In addition to NP effects, this Lagrangian also includes the LO and NLO SM vertices, for example the parameter $\delta c_V = 1$ corresponds to the tree-level coupling between the Higgs field and the EW bosons $V = W, Z$. While the coupling $c_{gg} = 4/3$ corresponds to the SM effective coupling at NLO if the heavy top limit (HTL) $m_t \rightarrow \infty$. In contrast to eqs. (??) and (??) the couplings of one and two Higgs bosons to fermions or gluons become de-correlated. Giving this Lagrangian a richer phenomenology for Higgs pair production.

The HEFT coefficients modifying the Higgs pair production via gluon fusion are

$$c_{hh}, \textcolor{blue}{c_t} \text{ (a)}, \textcolor{teal}{c_{tt}} \text{ (b)}, \textcolor{red}{c_{gg}} \text{ (c)}, \textcolor{red}{c_{gg}^{(2)}} \text{ (d)}, \quad (3.15)$$

with the same colours highlighted in the operator insertions of Figure 3.3 and the letter next to the coefficient indicates the diagram its operator contributes to. Full parametrisation of the Higgs pair cross-section at NLO (inclusive and differential) and NNLO (inclusive) can be found in refs. [154–156] and implemented at NLO in **POWHEG-BOX** [157]. UV-complete models that yield in the EWChL are composite Higgs models [136, 137, 158], dilaton theories [159], techni-dilaton models [160], technicolour models [161] and other models with induced EW symmetry breaking [162, 163].

3.2.1 Translation between SMEFT and HEFT

In order to facilitate the translation between SMEFT and HEFT or to the κ -formalism, one needs to put the SMEFT Lagrangian into the canonical form, that is to convert the operators with covariant derivatives acting on the Higgs to canonically normalised Higgs kinetic term. This is done done by the field redefinition.

$$\phi = \begin{pmatrix} 0 \\ h(1 + c_{h,kin}) + v \end{pmatrix} \quad (3.16)$$

with

$$c_{h,kin} = \left(C_{\phi,\square} - \frac{1}{4} C_{\phi D} \right) \frac{v^2}{\Lambda^2}. \quad (3.17)$$

This field redefinition will generate derivative interactions of the form $h(\partial_\mu h)^2$ and $h^2(\partial_\mu h)^2$. In order to remove these terms, and for sake of simplicity one needs to use a gauge-dependent field redefinition²

$$h \rightarrow h + c_{h,kin} \left(h + \frac{h^2}{v} + \frac{h^3}{3v^2} \right). \quad (3.18)$$

This field redefinition hence leads to a dependence on $c_{h,kin}$ of all Higgs boson couplings. There are however some caveats to the translation between HEFT and SMEFT, for

²For gauge-independent formalism cf. [164].

example, HEFT is less restrictive than SMEFT and it covers loop effects. This makes some points of the HEFT parameter space unmappable to SMEFT. In addition, the power counting is different in both formalisms, as mentioned before there will be some operators present in SMEFT that are absent in HEFT and vice-versa. In [Table 3.2](#), the translation between the HEFT and SMEFT Wilson coefficients of the operators relevant to Higgs pair production at LO is shown. More general translation between

HEFT	SMEFT (Warsaw)
c_{hh}	$1 - 2 \frac{v^4}{m_h^2} C_\phi + 3c_{h,kin}$
c_f	$1 + c_{h,kin} - C_{f\phi} \frac{v^3}{\sqrt{2}m_f}$
c_{ff}	$-C_{f\phi} \frac{3v^3}{2\sqrt{2}m_f} + c_{h,kin}$
c_{gg}	$8\pi/\alpha_s v^2 C_{\phi G}$
$c_{gg}^{(2)}$	$4\pi/\alpha_s v^2 C_{\phi G}$

Table 3.2. Translation between the Wilson coefficients of HEFT and SMEFT for the operators relevant to Higgs pair production

SMEFT in Warsaw and SILH basis and HEFT can be done automatically using [Rosetta](#) package [\[165\]](#)

3.2.2 EFT and κ -formalism

The κ formalism provides an experimentally accessible and well-defined in terms of QFT way to study the Higgs properties [\[166\]](#). The κ parameters are part of more generalised formalism called the Higgs **Pseudo-observables** (PO's), which is discussed in [??](#).

If the new physics contributions do not generate new Lorentz structures there is a possible translation between the Wilson coefficients in the SMEFT Warsaw basis, and the κ formalism. In particular, taking the rescaling of the trilinear coupling, κ_λ , the translation is given by

$$\kappa_\lambda = 1 - \frac{v^4}{m_h^2} \frac{C_\phi}{\Lambda^2} + 3c_{h,kin}, \quad (3.19)$$

A similar relation exists for the rescaling of the quark Yukawa couplings κ_q

$$\kappa_q = 1 + c_{h,kin} - \frac{v^3}{\sqrt{2}m_q} \frac{C_{q\phi}}{\Lambda^2}. \quad (3.20)$$

One can see the similarities between κ -formalism and HEFT in these two examples, but this is not always the case. Other translations could be obtained by comparing how SMEFT operators modify the Higgs couplings with the SM, and matching it with the corresponding κ or other Higgs PO's.

However, one should be careful while interpreting results quoted in terms of Wilson

coefficients in the SMEFT framework extracted from di-Higgs, multi-Higgs or multi-vector bosons searches, as these results include couplings that are not present in the SM. For example, the $hhq\bar{q}$ coupling, though being linearly related to the quark Yukawa coupling $hq\bar{q}$, is not a rescaling of any SM Higgs coupling as has been discussed in ???. With this in mind, one can strictly remain within a linear EFT and link the rescaling of the quark Yukawa, κ_q , to the $hhq\bar{q}$ coupling through

$$g_{hhq\bar{q}}^{\text{linear-EFT}} = -\frac{3}{2} \frac{1-\kappa_q}{v} g_{hq\bar{q}}^{\text{SM}}. \quad (3.21)$$

This relation will no longer hold once a non-linear EFT, like HEFT, is used. Hence, the κ -formalism, in a strict sense, is not applicable to multi-Higgs studies.

3.3 Conclusions

Effective field theories provide a systematic yet simplified approach for NP searches by simplifying its complex interaction structures. This can be thought of as a dimensionality reduction approach by collapsing all the NP interaction into their effective ones as observed at colliders with energy reaches below the NP scale Λ . The linear approach to EFT is called the SMEFT, which preserves the SM fields and symmetries and the Higgs boson is a part of an $SU(2)_L$ doublet ϕ like the SM case. While non-linear approaches such as the chiral EW Lagrangian (or HEFT) treats the Higgs boson as an added singlet. The latter approach is more general and introduces independent parameters involving multiple Higgs bosons. For example, the couplings $f\bar{f}h$ and $f\bar{f}hh$ will be both generated in SMEFT and HEFT, but in SMEFT they are related by the Wilson coefficient $C_{\phi f}$, while in HEFT they have independent Wilson coefficients c_f and c_{ff} respectively.

Most of the Wilson coefficients involving Higgs interactions are strongly bounds by EWPO's, Higgs and top data. In addition to theoretical bounds found in [167]. However, the Wilson coefficients modifying the Higgs self-couplings, though bounds from the first two aforementioned data and perturbative unitarity [52, 168] exist, these bounds remain weak. This can be improved by the searches for Higgs pair production at the HL-LHC, as this process is far more sensitive to these Wilson coefficients than EWPO and single-Higgs data, as they only appear at NLO in the theoretical predictions of the later two experimental observables. In ??, I show the best bounds on the Wilson coefficients relevant to Higgs production as well as heavy quark four-fermion operators, with a heatmap indicating the contribution of each operator in prominent Higgs, top and EW precision observables. Although this is a subset of the total SMEFT operators and observables used in the fits, one can see the interconnectivity of the measurements. The main objective of this thesis is to extend these connections by exploiting the potential of single-Higgs data and Higgs pair production to constrain the Higgs trilinear coupling modifiers (mainly in SMEFT) and the interplay between C_ϕ and heavy quark four-fermion operators in single Higgs data. Moreover, the SMEFT picture can be further extended by unravelling interplay between Light quark couplings modifiers in

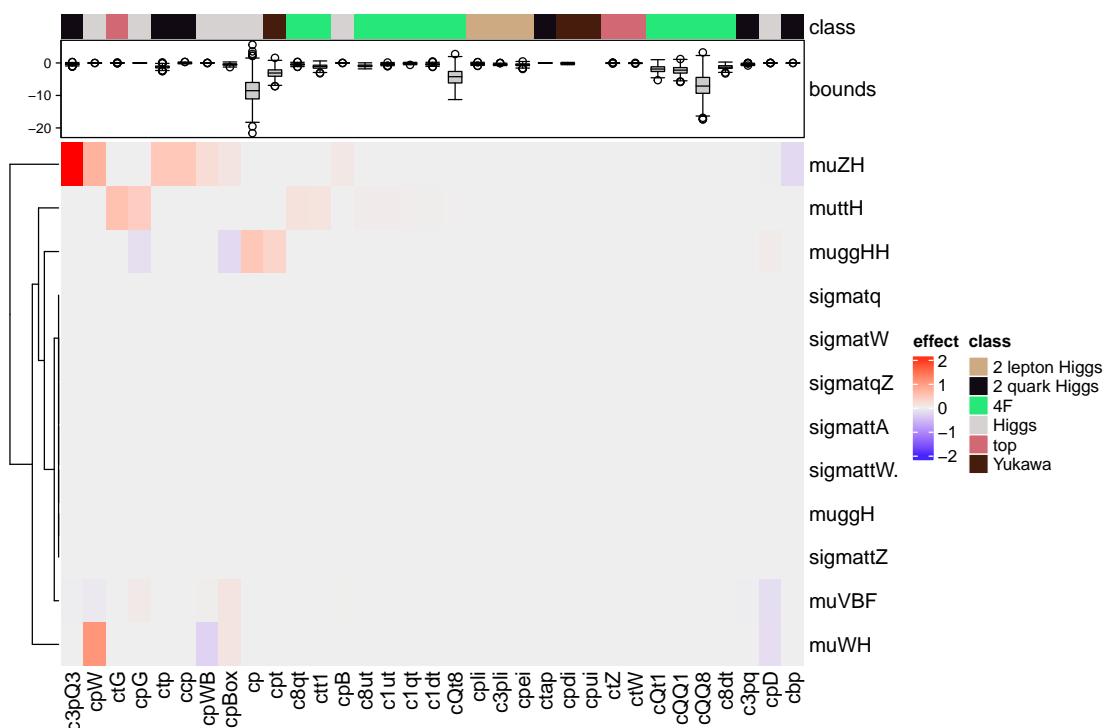

Figure 3.5

Higgs pair production. Lastly, I will show another connection between Higgs operators in SMEFT and flavour anomalies. Emphasising the complex interconnectivity between experimental observables and SMEFT operators.

4 Virtual two-loop calculation of Zh production via gluon fusion

As we have seen in section 2.3, Higgs couplings to the weak vector bosons, i.e. Z and W is approaching the precision level. For their measurements both VBF and Vh channels are used, the associated Higgs production with the vector bosons are not only important for measuring the VVh coupling but also other couplings and properties as discussed in ???. The most notable example emphasising the importance of this channel is the measurement of the Higgs decaying to beauty quarks $h \rightarrow b\bar{b}$ by both ATLAS and CMS [169, 170]. Hence, the Vh Higgs production is an important channel to look for in the future runs of the LHC. As the statistical and systematic uncertainties coming from the experimental setup of the LHC will be eventually reduced in the future runs, due to higher integrated luminosity, upgraded detectors and improved analysis techniques. There is an exigency to reduce theoretical uncertainties emerging from the perturbative calculations of cross-sections. In order to accomplish that, one should include higher order terms to the theoretical prediction. Since Wh production has no gluon fusion channel, and the main source of Zh uncertainties actually come from its gluon fusion part. Higher order correction to the $gg \rightarrow Zh$ is the key to improve the theoretical modelling for Vh .

It should be noted that the Zh channel can receive contributions from new particles [171], particularly at the large invariant-mass region where the gluon fusion contribution becomes more important, and HTL approximation would typically fail. Therefore, better understanding of the SM prediction of the Zh gluon fusion channel is crucial for both the SM precision measurements of Higgs production within the SM and for testing NP in this channel, e.g. new vector-like leptons.

This chapter aims to demonstrate the use of p_T -expansion technique, developed in [172] as an approach to compute the two-loop virtual corrections to $gg \rightarrow Zh$ analytically, including top mass effects. This method also allows for the use of Padé approximants, in order to extend the range of validity of this calculation.cite the paper once it is out

This chapter is structured as follows : In section 4.1 contains the general notation we have used for the gluon fusion Zh process calculation. Then, in subsection 4.1.1 the transverse momentum expansion method is discussed. Calculation of the LO form-factors in the transverse momentum expansion is illustrated in section 4.2 as a proof of concept for the p_T -expansion technique. Outline of the two-loop calculation is discussed in section 4.3. Finally, in section 4.4, the results of our calculation are shown with concluding remarks at the end. This chapter is based on the work my collaborators and I have published in [173].

4.1 General notation

The amplitude $g_a^\mu(p_1)g_b^\nu(p_2) \rightarrow Z^\rho(p_3)h(p_4)$ can be written as

$$\mathcal{A} = i\sqrt{2}\frac{m_Z G_F \frac{\alpha_s^0}{4\pi}(\mu_R)}{\pi} \delta_{ab} \epsilon_\mu^a(p_1) \epsilon_\nu^b(p_2) \epsilon_\rho(p_3) \hat{\mathcal{A}}^{\mu\nu\rho}(p_1, p_2, p_3), \quad (4.1)$$

$$\hat{\mathcal{A}}^{\mu\nu\rho}(p_1, p_2, p_3) = \sum_{i=1}^6 \mathcal{P}_i^{\mu\nu\rho}(p_1, p_2, p_3) \mathcal{A}_i(\hat{s}, \hat{t}, \hat{u}, m_t, m_h, m_Z), \quad (4.2)$$

where μ_R is the renormalisation scale and $\epsilon_\mu^a(p_1) \epsilon_\nu^b(p_2) \epsilon_\rho(p_3)$ are the polarization vectors of the gluons and the Z boson, respectively. It is possible to decompose the amplitude into a maximum of 6 Lorentz structures encapsulated by the tensors $\mathcal{P}_i^{\mu\nu\rho}$. Due to the presence of the γ_5 these projectors are proportional to the Levi-Civita total anti-symmetric tensor $\epsilon^{\alpha\beta\gamma\delta}$. One can choose to an orthogonal basis explicitly shown in ??, such that

$$\mathcal{P}_i^{\mu\nu\rho} \mathcal{P}_{j\mu\nu\rho} = 0, \quad \text{for } i \neq j \quad (4.3)$$

By this choice one obtains unique form factors corresponding to each projector

$$\mathcal{A}_i(\hat{s}, \hat{t}, \hat{u}, m_t, m_h, m_Z), \quad (4.4)$$

that are multivariate complex functions of the top (m_t), Higgs (m_h) and Z (m_Z) bosons masses, and of the partonic Mandelstam variables

$$\hat{s} = (p_1 + p_2)^2, \quad \hat{t} = (p_1 + p_3)^2, \quad \hat{u} = (p_2 + p_3)^2, \quad (4.5)$$

where $\hat{s} + \hat{t} + \hat{u} = m_Z^2 + m_h^2$ and all the momenta are considered to be incoming. The form-factors \mathcal{A}_i can be perturbatively expanded in orders of α_s ,

$$\mathcal{A}_i = \sum_{k=0} \left(\frac{\alpha_s}{\pi} \right)^k \mathcal{A}_i^{(k)} \quad (4.6)$$

Where $\mathcal{A}_i^{(0)}$ and $\mathcal{A}_i^{(1)}$ are the LO and NLO terms, respectively. Using Fermi's Golden Rule, we can write the Born partonic cross-section as

$$\hat{\sigma}^{(0)}(\hat{s}) = \frac{m_Z^2 G_F^2 \alpha_s(\mu_R)^2}{64\hat{s}^2(2\pi)^3} \int_{\hat{t}-}^{\hat{t}+} d\hat{t} \sum_i |\mathcal{A}_i^{(0)}|^2, \quad (4.7)$$

where $\hat{t}^\pm = [-\hat{s} + m_h^2 + m_Z^2 \pm \sqrt{(\hat{s} - m_h^2 - m_Z^2)^2 - 4m_h^2 m_Z^2}] / 2$.

The LO has two sets of diagrams, the triangle, and box diagrams shown in Figure 4.1. In (a), the triangle diagrams contain a neutral Goldstone boson G^0 , instead in (b) the Z boson is mediated. The interplay between these two diagram types depends on the ξ gauge. Moreover, the Z boson is strictly off-shell, due to Furry's theorem. In the Landau gauge the Z -mediated diagrams will also vanish, this can be seen by considering the

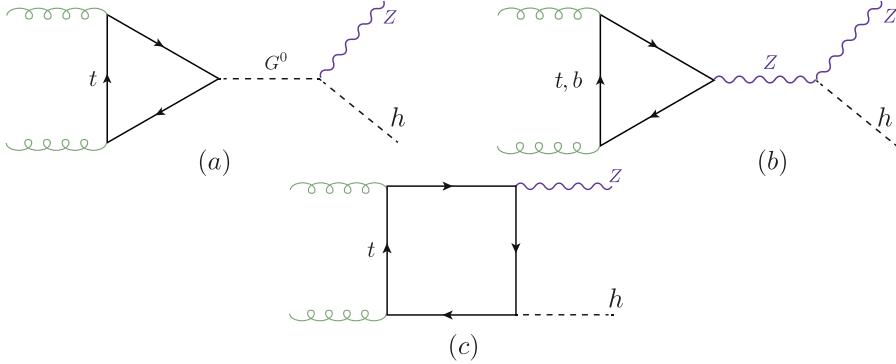

Figure 4.1. Feynman diagrams type for the LO $gg \rightarrow Z h$ process. The triangle diagrams in a general ξ gauge involve Z and the neutral Goldstone G^0 propagators.

subamplitude ggZ^* which in the Landau gauge can be related to the decay of a massive vector boson with mass $\sqrt{\hat{s}}$ into two massless ones, a process that is forbidden by the Landau-Yang theorem [174, 175]. The triangle diagrams are also proportional to the mass difference between the up and down type quarks. In this calculation, the first and second generation quarks are assumed to be massless, as well as the b quark, hence light quarks loops do not contribute to this process. The same would apply to the box diagrams (c), as they are proportional to the quark Yukawa coupling, and vanish in the massless quarks case. Moreover, triangle diagrams with $b-$ quark loops contribute to $\sim 1\%$ of the total amplitude, computed in the limit $m_b \rightarrow 0$.

4.1.1 The transverse momentum expansion

Choosing to expand in small p_T of the Z boson, the first step is expressing p_T in terms of the Mandelstam variables and masses

$$p_T^2 = \frac{\hat{t}\hat{u} - m_Z^2 m_h^2}{\hat{s}}. \quad (4.8)$$

From eq.(4.8), together with the relation between the Mandelstam variables, one finds

$$p_T^2 + \frac{m_h^2 + m_Z^2}{2} \leq \frac{\hat{s}}{4} + \frac{\Delta_m^2}{\hat{s}}, \quad (4.9)$$

where $\Delta_m = (m_h^2 - m_Z^2)/2$. Eq.(4.9) implies $p_T^2/\hat{s} < 1$ that, together with the kinematical constraints $m_h^2/\hat{s} < 1$ and $m_Z^2/\hat{s} < 1$. With these relations in mind, one can expand the amplitudes in terms of small p_T^2/\hat{s} , m_h^2/\hat{s} and m_Z^2/\hat{s} , which is technically valid throughout the whole phase space, contrary to the LME and HE limits. The caveat for this expansion is that, the amplitude does not depend on p_T explicitly. Instead, one would expand in

the reduced Mandelstam variables $t'/s' \ll 1$ or $u'/s' \ll 1$, defined as

$$s' = p_1 \cdot p_2 = \frac{\hat{s}}{2}, \quad t' = p_1 \cdot p_3 = \frac{\hat{t} - m_Z^2}{2}, \quad u' = p_2 \cdot p_3 = \frac{\hat{u} - m_Z^2}{2} \quad (4.10)$$

and satisfy

$$s' + t' + u' = \Delta_m. \quad (4.11)$$

The choice of the expansion parameter t' or u' depends whether one expands in the forward or backwards kinematics. Because the process $gg \rightarrow Zh$, has two particles in the final states with different masses, the amplitude is not symmetric under the their exchange. One therefore cannot compute the cross-section by integrating only the forward-expanded amplitude [173], contrary what has been done for the Higgs pair [172]. In order to overcome this issue, one could further examine the projectors in ?? and observe that they can be split into symmetric and anti-symmetric parts with respect to the exchange $t' \leftrightarrow u'$. Then, expand the symmetric part in the forward kinematics, like the Higgs pair case. As for the anti-symmetric part, the antisymmetric factor is simply extracted by multiplying the form-factors by $1/(\hat{t} - \hat{u})$, written as $1/(2s' - 4t' - 2\Delta_m)$, then perform the expansion in the forward kinematics and finally multiply back by $(\hat{t} - \hat{u})$.

In order to implement the p_T -expansion at the Feynman diagrams level we start by splitting the momenta into longitudinal and transverse with respect to the beam direction, by introducing the vector [172],

$$r^\mu = p_1^\mu + p_3^\mu, \quad (4.12)$$

which satisfies

$$r^2 = \hat{t}, \quad r \cdot p_1 = \frac{\hat{t} - m_Z^2}{2}, \quad r \cdot p_2 = -\frac{\hat{t} - m_h^2}{2}, \quad (4.13)$$

and hence can be also written as

$$r^\mu = -\frac{\hat{t} - m_h^2}{\hat{s}} p_1^\mu + \frac{\hat{t} - m_Z^2}{\hat{s}} p_2^\mu + r_\perp^\mu = \frac{t'}{s'} (p_2^\mu - p_1^\mu) - \frac{\Delta_m}{s'} p_1^\mu + r_\perp^\mu, \quad (4.14)$$

where

$$r_\perp^2 = -p_T^2. \quad (4.15)$$

substituting the definition of p_T from eq.(4.8) one obtains

$$t' = -\frac{s'}{2} \left\{ 1 - \frac{\Delta_m}{s'} \pm \sqrt{\left(1 - \frac{\Delta_m}{s'}\right)^2 - 2\frac{p_T^2 + m_Z^2}{s'}} \right\} \quad (4.16)$$

implying that the expansion in small p_T (the minus sign case in eq.(4.16)) can be realized at the level of Feynman diagrams, by expanding the propagators in terms of the vector r^μ around $r^\mu \sim 0$ or, equivalently, $p_3^\mu \sim -p_1^\mu$, see eq.(4.14).

4.2 Born cross-section in the p_T -expansion

As a baseline test for the validity and convergence behaviour of the p_T expansion we start by computing the LO amplitude, and consequently the Born partonic cross-section in the p_T expansion then compare it with the exact results found in [176, 177].

Starting by defining the one-loop functions appearing in the similar calculation of the Born cross-section for $gg \rightarrow hh$ in the same expansion carried out in ref. [172]

$$B_0[\hat{s}, m_t^2, m_t^2] \equiv B_0^+, \quad B_0[-\hat{s}, m_t^2, m_t^2] \equiv B_0^-, \quad (4.17)$$

$$C_0[0, 0, \hat{s}, m_t^2, m_t^2, m_t^2] \equiv C_0^+, \quad C_0[0, 0, -\hat{s}, m_t^2, m_t^2, m_t^2] \equiv C_0^- \quad (4.18)$$

$$B_0[q^2, m_1^2, m_2^2] = \frac{1}{i\pi^2} \int \frac{d^n k}{\mu^{n-4}} \frac{1}{(k^2 - m_1^2)((k+q)^2 - m_2^2)}, \quad (4.19)$$

$$C_0[q_a^2, q_b^2, (q_a + q_b)^2, m_1^2, m_2^2, m_3^2] = \frac{1}{i\pi^2} \int \frac{d^d k}{\mu^{d-4}} \frac{1}{[k^2 - m_1^2][(k+q_a)^2 - m_2^2][(k-q_b)^2 - m_3^2]} \quad (4.20)$$

are the Passarino-Veltman functions [178], with d the dimension of spacetime and μ the 't Hooft mass. There are only two non-vanishing form-factors at LO, one is symmetric \mathcal{A}_2 , and the other is antisymmetric \mathcal{A}_6 , in the p_T -expansion, these form-factors are give by,

up to order $\mathcal{O}(p_T^2)$

$$\begin{aligned}
 \mathcal{A}_2^{(0,\Delta)} &= -\frac{p_T}{\sqrt{2}(m_Z^2 + p_T^2)}(\hat{s} - \Delta_m)m_t^2 C_0^+, \\
 \mathcal{A}_2^{(0,\square)} &= \frac{p_T}{\sqrt{2}(m_Z^2 + p_T^2)} \left\{ \right. \\
 &\quad \left(m_t^2 - m_z^2 \frac{\hat{s} - 6m_t^2}{4\hat{s}} - p_T^2 \frac{12m_t^4 - 16m_t^2\hat{s} + \hat{s}^2}{12\hat{s}^2} \right) B_0^+ \\
 &- \left(m_t^2 - \Delta_m \frac{m_t^2}{(4m_t^2 + \hat{s})} + m_z^2 \frac{24m_t^4 - 6m_t^2\hat{s} - \hat{s}^2}{4\hat{s}(4m_t^2 + \hat{s})} - \right. \\
 &\quad \left. p_T^2 \frac{48m_t^6 - 68m_t^4\hat{s} - 4m_t^2\hat{s}^2 + \hat{s}^3}{12\hat{s}^2(4m_t^2 + \hat{s})} \right) B_0^- \\
 &+ \left(2m_t^2 - \Delta_m + m_z^2 \frac{3m_t^2 - \hat{s}}{\hat{s}} + p_T^2 \frac{3m_t^2\hat{s} - 2m_t^4}{\hat{s}^2} \right) m_t^2 C_0^- \\
 &+ \left(\hat{s} - 2m_t^2 + m_z^2 \frac{\hat{s} - 3m_t^2}{\hat{s}} + p_T^2 \frac{2m_t^4 - 3m_t^2\hat{s} + \hat{s}^2}{\hat{s}^2} \right) m_t^2 C_0^+ \\
 &+ \log \left(\frac{m_t^2}{\mu^2} \right) \frac{m_t^2}{(4m_t^2 + \hat{s})} \left(\Delta_m + 2m_z^2 + p_T^2 \frac{2\hat{s} - 2m_t^2}{3\hat{s}} \right) \\
 &- \left. \Delta_m \frac{2m_t^2}{(4m_t^2 + \hat{s})} + m_z^2 \frac{\hat{s} - 12m_t^2}{4(4m_t^2 + \hat{s})} + p_T^2 \frac{8m_t^4 - 2m_t^2\hat{s} + \hat{s}^2}{4\hat{s}(4m_t^2 + \hat{s})} \right\},
 \end{aligned} \tag{4.22}$$

and

$$\mathcal{A}_6^{(0,\Delta)} = 0, \tag{4.23}$$

$$\begin{aligned}
 \mathcal{A}_6^{(0,\square)} &= \frac{\hat{t} - \hat{u}}{\hat{s}^2} p_T \left[\frac{m_t^2}{2} \left(B_0^- - B_0^+ \right) - \frac{\hat{s}}{4} \right. \\
 &- \left. \frac{2m_t^2 + \hat{s}}{2} m_t^2 C_0^- + \frac{2m_t^2 - \hat{s}}{2} m_t^2 C_0^+ \right],
 \end{aligned} \tag{4.24}$$

where these form-factors were divided into triangle (Δ) and box (\square) contributions, and B_0 functions are understood as the finite part of the integrals on the right hand side of eq.(4.19).

Using several truncations of the p_T -expansion, and comparing it to the exact LO result, one can see in Figure 4.2 the exact Born partonic LO cross section (red line) as a function of the invariant mass of the Zj system, M_{Zh} , in comparison to the p_T -expansions. For the numerical evaluation of the cross section here and in the following, we used as SM

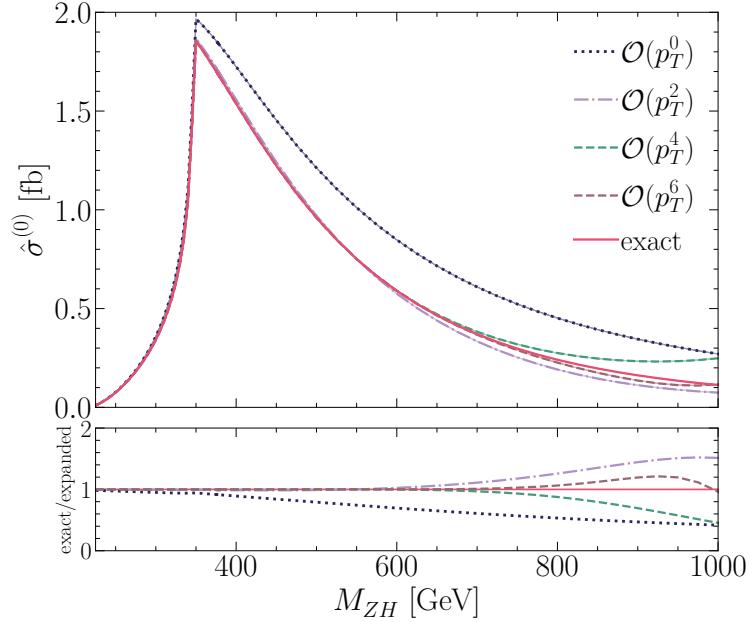

Figure 4.2. The Born partonic cross-section as a function of the invariant mass M_{Zh} . The exact (red line) is plotted together with results at different orders in the p_T -expansion (dashed lines). In the bottom part, the ratio of the full result over the p_T -expanded one at various orders is shown. This plot has been already published in [173]

input parameters

$$\begin{aligned} m_Z &= 91.1876 \text{ GeV}, & m_h &= 125.1 \text{ GeV}, & m_t &= 173.21 \text{ GeV}, \\ m_b &= 0 \text{ GeV}, & G_F &= 1.16637 \text{ GeV}^{-2}, & \alpha_s(m_Z) &= 0.118. \end{aligned}$$

From the ratio plotted in the lower panel of Figure 4.2, we observe that the $\mathcal{O}(p_T^0)$ expansion is in good agreement with the exact result when $M_{Zh} \lesssim 2m_t$. Inclusion of higher order terms up to $\mathcal{O}(p_T^6)$ extended the validity of the expansion to reach $M_{Zh} \lesssim 750$ GeV. This is the similar behaviour seen in [172] for Higgs pair. Therefore, one would expect the p_T -expanded two-loop virtual correction to be an accurate approximation with the exact (numerical) result for the region of the invariant mass of $M_{Zh} \sim 700 - 750$ GeV. Similar conclusions can be seen more explicitly in Table 4.1, where it is shown that the partonic cross-section at $\mathcal{O}(p_T^4)$ agrees with the full result for $M_{ZH} \lesssim 600$ GeV on the permille level and the agreement further improves when $\mathcal{O}(p_T^6)$ terms are included.

M_{Zh} [GeV]	$\mathcal{O}(p_T^0)$	$\mathcal{O}(p_T^2)$	$\mathcal{O}(p_T^4)$	$\mathcal{O}(p_T^6)$	full

Table 4.1. The partonic cross section $\hat{\sigma}^{(0)}$ at various orders in p_T and the full computation for several values of M_{Zh} . This table has been already published in [173].

4.3 NLO calculation

The virtual two-loop corrections to $gg \rightarrow Zh$ are shown in Figure 4.3, which involve corrections to the triangle topology in (a) and (b). The corrections to the box topology in (c) and a new topology , dented by double triangle in (d). Both two-loop corrections to the triangles, and the double triangle diagrams can be computed exactly analytically. However, the two-loop box diagrams contain master-integrals (MI's) that have no analytic solutions, so far. The two-loop box diagrams will be computed in the p_T -expansion.

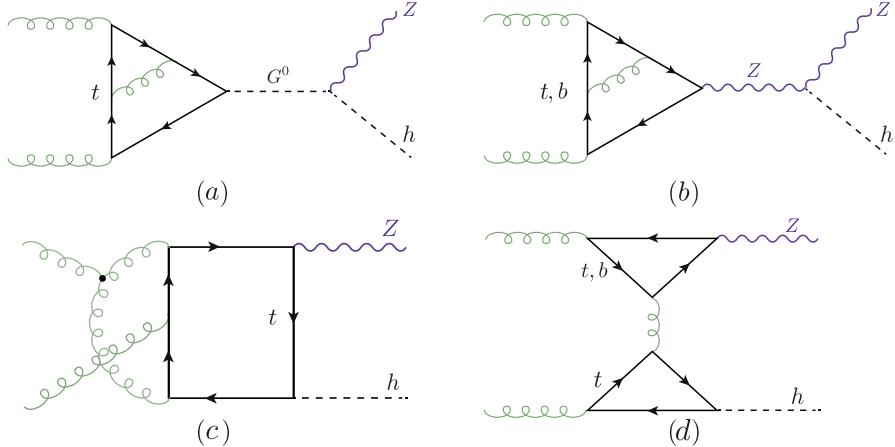

Figure 4.3. Feynman diagrams types for the virtual NLO corrections to the $gg \rightarrow Zh$ process.

4.3.1 Renormalisation

The two-loop corrections to the triangle and box diagrams contain both UV and IR divergences. The first emerges from UV divergent sub-diagrams, such as top mass renormalisation and QCD vertex correction. While the IR divergences come from massless

loops. In order to remove these divergences, one introduces adequate counter-terms. On the other hand, the double triangle is both UV and IR finite.

We start by the gluon wavefunction renormalisation of the incoming gluons (external legs) such that the amplitude is renormalised by $Z_A^{1/2}$ for each gluon.

$$Z_A = 1 + \frac{\alpha_s^0}{4\pi} \frac{2}{3\epsilon} \left(\frac{\mu_R^2}{m_t^2} \right)^\epsilon. \quad (4.25)$$

The on-shell scheme for the top mass renormalisation has been used, in which the bare mass is replaced by the renormalised one $m_0 = Z_m m$ in the propagators this gives the $\overline{\text{MS}}$ renormalised mass.

$$Z_m = 1 + C_F \frac{3}{\epsilon}. \quad (4.26)$$

In order to convert the mass definition to the on-shell scheme we add the finite renormalisation term

$$Z_m^{OS} = 1 - 2C_F, \quad (4.27)$$

here $C_F = (N_c^2 - 1)/2N_c$ is one of the two Casimir invariants of QCD along with $C_A = N_c$. The $q\bar{q}g$ vertex correction involves a renormalisation of the strong couplings constant α_s which is done via replacing the bare constant α_s^0 with the renormalised one, hence it becomes $\alpha_s^0 = \frac{\mu_R^{2\epsilon}}{S_\epsilon} Z_{\alpha_s} \alpha_s$, where

$$Z_{\alpha_s} = 1 - \frac{\alpha_s}{4\pi} \frac{1}{\epsilon} \left(\beta_0 - \frac{2}{3} \right) \left(\frac{\mu_R^2}{m_t^2} \right)^\epsilon, \quad (4.28)$$

and the constant $\beta_0 = \frac{11}{3}C_A - \frac{2}{3}N_f$, where N_f is the number of “active” flavours. The 5-flavour scheme $N_f = 5$ is adopted here.

The loop integrals were evaluated via dimensional regularisation in $d = 4 - 2\epsilon$ dimensions. Which requires some caution when γ_5 is present in the amplitude. We let γ_5 naively anti-commute with all d -dimensional γ_μ 's and then correct that with the finite renormalisation constant known as **Larin counter-term** [179]

$$Z_5 = 1 - 2C_F. \quad (4.29)$$

The renormalised amplitude is written as

$$\mathcal{M}(\alpha_s, m, \mu_R) = Z_A \mathcal{M}(\alpha_s^0, m^0). \quad (4.30)$$

Putting all the above substitutions together, we get the renormalised two-loop form-

factor:

$$(\mathcal{A}^{(1)})^R = \mathcal{A}^{(1)} - \mathcal{A}_{UV}^{(0)} - \mathcal{A}_{UV,m}^{(0)} + \mathcal{A}_{\text{Larin}}^{(0)} \quad (4.31)$$

$$\mathcal{A}_{UV}^{(0)} = \frac{\alpha_s}{4\pi} \frac{\beta_0}{\epsilon} \left(\frac{\mu_R^2}{\hat{s}} \right)^{-\epsilon} \mathcal{A}^{(0)}.$$

$$\mathcal{A}_{UV,m}^{(0)} = \frac{\alpha_s}{4\pi} \left(\frac{3}{\epsilon} - 2 \right) C_F \left(\frac{\mu_R^2}{\hat{s}} \right)^{-\epsilon} m^0 \partial_m \mathcal{A}^{(0)}. \quad (4.32)$$

$$\mathcal{A}_{\text{Larin}}^{(0)} = -\frac{\alpha_s}{4\pi} C_F \mathcal{A}^{(0)}.$$

The following IR-counter-term is used in order to cancel the IR divergences.

$$\mathcal{A}_{IR}^{(0)} = \frac{e^{\gamma_E \epsilon}}{\Gamma(1-\epsilon)} \frac{\alpha_s}{4\pi} \left(\frac{\beta_0}{\epsilon} + \frac{C_A}{\epsilon^2} \right) \left(\frac{\mu_R^2}{\hat{s}} \right)^{2\epsilon} \mathcal{A}^{(0)} \quad (4.33)$$

The one-loop form-factors, need to be expanded up to order $\mathcal{O}(\epsilon^2)$, for the UV and IR counter-terms.

4.3.2 Calculation of the exact virtual corrections

The two-loop calculations of the triangle diagrams involves the diagrams of with virtual Z^* and G^0 , depending on the gauge of choice. Observations found in ref.[180] shows that due to Landau-Yang theorem in the Landau gauge the diagrams with the Z^* exchange vanishes. Therefore, the part of the top triangle diagrams can be obtained from the decay amplitude of a pseudoscalar boson into two gluons which is known in the literature in the full mass dependence up to NLO terms [181, 182]. On the contrary, in the unitary gauge, the NLO calculation needs to be done with the Z^* exchange diagrams only. The calculations result in apparently different Lorentz structures, that are linked via the Schouten identity

$$q^\alpha \epsilon^{\beta\gamma\delta\phi} + q^\beta \epsilon^{\gamma\delta\phi\alpha} + q^\gamma \epsilon^{\delta\phi\alpha\beta} + q^\gamma \epsilon^{\delta\phi\alpha\beta} + q^\delta \epsilon^{\phi\alpha\beta\gamma} + q^\phi \epsilon^{\alpha\beta\gamma\delta} = 0 \quad (4.34)$$

A cross-check has been preformed in order to ensure that the NLO calculation introduces no new Lorentz structures, and gives the same result in a general R_ξ gauge as the results in [181, 182]. The two-loop calculation has been carried out in R_ξ gauge. The amplitudes have been automatically generated by **FeynArts** [183] and contracted with the projectors as defined in ?? using **FeynCalc** [184, 185] and **Package X** [186] and in-house Mathematica routines. The two-loop integrals were reduced to a set of master integrals MI, illustrated graphically in Figure 4.4 using **Kira** [187]. These MI's are either products of one-loop functions (a)-(c), (e),(f),(h) and (l) or can be found in the literature [182, 188]. Their implementation in our calculation has been validated numerically using **SecDec** [189, 190]. The virtual correction for the triangle diagrams

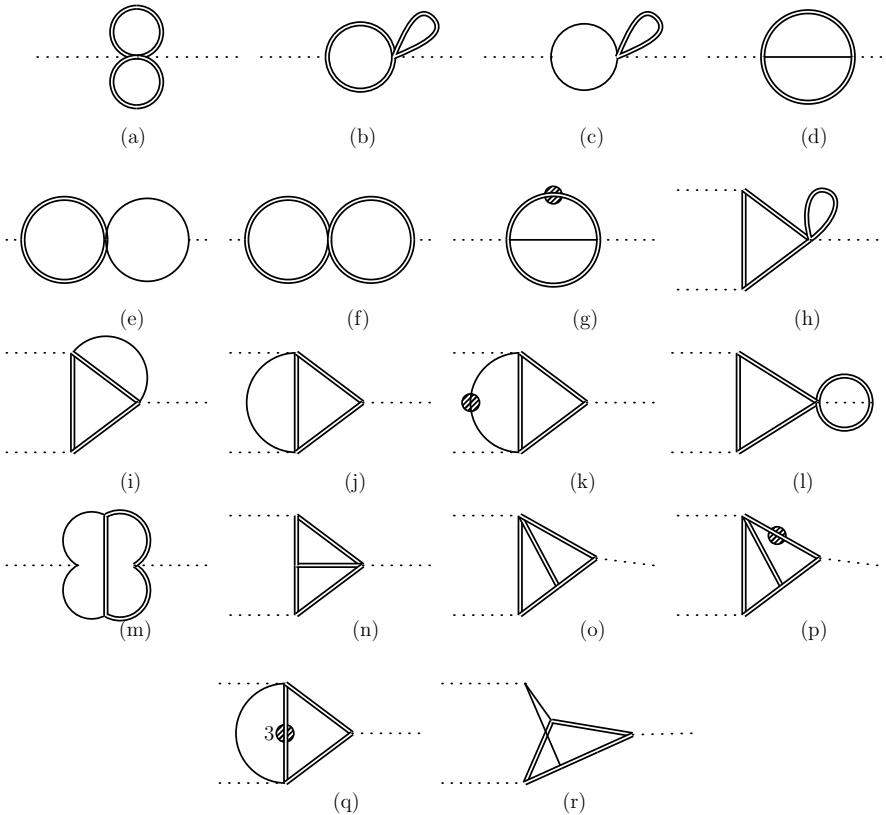

Figure 4.4. The list of two-loop master integrals (MI's) resulting from the reduction of the two-loop triangle corrections, and the product of one-loop MI's appearing in this list also appear in the calculation of the double-triangle diagrams. A single line denotes a massless propagator, while a double line denotes a massive one. The dot denotes a squared propagator, unless the number of the exponent is indicated, here only 3 appears in diagram (q).

can be separated according to their colour factors into

$$\mathcal{A}^{(1)} = C_F \mathcal{A}_{CF}^{(1)} + C_A \mathcal{A}_{CA}^{(1)}, \quad (4.35)$$

The C_A part contains a double pole $\mathcal{O}(1/\epsilon^2)$ and a single pole $\mathcal{O}(1/\epsilon)$, both coming from the IR divergence. Whilst the C_F part contains a UV divergent pole that needs to be cured via mass renormalisation. The poles do not have a dependence on the renormalisation scale μ_R . However, there is a dependence on that scale in the finite part, as well. No new Lorentz structures appeared, and the final result in R_ξ matched the one found in [181, 182] for the Landau gauge. The explicit results are shown in ??

The calculation of the double triangle diagrams (d) of Figure 4.3 is fairly straightforward, all of the integrals can be rewritten in terms of products of one-loop functions. All of the Lorentz structures appear in the double triangle except for \mathcal{P}_6 , analogous to the triangle case. The explicit forms of form-factors corresponding to these structures are presented in ???. Although we write the amplitude using a different tensorial structure with respect to ref.[191] we have checked, using the relations between the two tensorial structures reported in ???, that our result is in agreement with the one presented in ref.[192].

4.3.3 Calculation of the p_T -expanded virtual corrections

The two-loop triangle diagrams can also be interpreted as an expansion in p_T , but this expansion terminates at $\mathcal{O}(p_T^2)$, rather being an infinite series. Hence, in this section we concentrate on the two-loop box diagrams p_T -expansion ¹.

Similar to the two-loop triangle diagrams, the box diagrams amplitudes were generated projected through the same pipeline. After the contraction of the epsilon tensors the diagrams were expanded as described in subsection 4.1.1, keeping only $\mathcal{O}(p_T^4)$ terms. They were reduced to MI's using FIRE [193] and LiteRed [194]. The resulting MI's were identical to the one for Higgs pair production [172]. Nearly all of them are expressed in terms of generalised harmonic polylogarithms with the exception of two elliptic integrals [195, 196]. The renormalisation and IR pole subtraction procedure was carried out like prescribed subsection 4.3.1.

As a control, the two-loop box diagrams were also computed in the LME up to $\mathcal{O}(1/m_t^6)$. Since this expansion should be included within the p_T -expansion. We have retained the LME analytic expression by further expanding the p_T -expanded amplitude in small \hat{s}/m_t^2 . Providing an additional cross-check for the validity of the p_T -expansion.

4.4 Results and conclusions

The virtual corrections to the gluon fusion Zh production have been implemented in a FORTRAN code using `handyG` [197], for the evaluation of generalised harmonic polylogarithms, `Chaplin` [198] for the harmonic polylogarithms appearing in the triangle two-loop

¹The calculation of the box diagrams has been done mainly by my collaborators, the co-authors of [173]

Table 4.2. Comparison of $\mathcal{V}_{fin}4/(\alpha_s^2 \alpha^2)$ with the numerical results of ref.[199]. This plot has been already published in [173].

functions while the elliptic integrals are evaluated using the routines of ref.[196]. Since the result is analytic, the code is significantly faster than the numerical evaluation of the two-loop amplitude [199], with evalution time of ca. 0.5 min per one phase space point on a personal laptop.

In order to facilitate the comparison of our results with the ones presented in the literature, we define the finite part of the virtual corrections as in ref.[191]²

$$\begin{aligned} \mathcal{V}_{fin} = & \frac{G_F^2 m_Z^2}{16} \left(\frac{\alpha_s}{\pi} \right)^2 \left[\sum_i \left| \mathcal{A}_i^{(0)} \right|^2 \frac{C_A}{2} \left(\pi^2 - \log^2 \left(\frac{\mu_R^2}{\hat{s}} \right) \right) \right. \\ & \left. + 2 \sum_i \text{Re} \left[\mathcal{A}_i^{(0)} \left(\mathcal{A}_i^{(1)} \right)^* \right] \right] \end{aligned} \quad (4.36)$$

and in the numerical evaluation of eq.(4.36) we fixed $\mu_R = \sqrt{\hat{s}}$. Triangle and LME box topologies were validated against the results of refs.[191, 192] finding perfect agreement at the form-factor level, i.e. $\mathcal{A}_i^{(1)}$.

The virtual part of the partonic cross-section from the finite part of the virtual corrections in eq.(4.36) is defined by

$$\Delta \hat{\sigma}_{virt} = \int_{\hat{t}^-}^{\hat{t}^+} d\hat{t} \frac{\alpha_s}{16\pi^2} \frac{1}{\hat{s}^2} \mathcal{V}_{fin} \quad (4.37)$$

This function is used to confront p_T -expanded results. Starting with low M_{Zh} we have compared the p_T -expanded with the LME \mathcal{V}_{fin} , finding a good numerical agreement. It is important to note that, at the same order in the expansion, the p_T -expanded terms are more accurate than the LME ones, although computationally more demanding. Additional checks have been done using the numerical evaluation of the NLO amplitude by [199], where they have evaluated the exact two-loop MI's using `pySecDec` [200, 201]. Table 4.2 shows a comparison between our p_T -expanded $\mathcal{V}_{fin}4/(\frac{\alpha_s^0}{4\pi} \alpha^2)$ versus the exact numerical result of [199] for several phase space points. As can be seen from the table the relative difference between the two results is less than half a permille.

In Figure 4.5, the dashed lines show the different orders of the expansion. For all

²The definition of the matrix elements here differs by a factor of $\frac{1}{\hat{s}}$ from ref.[191], cf. also ??.

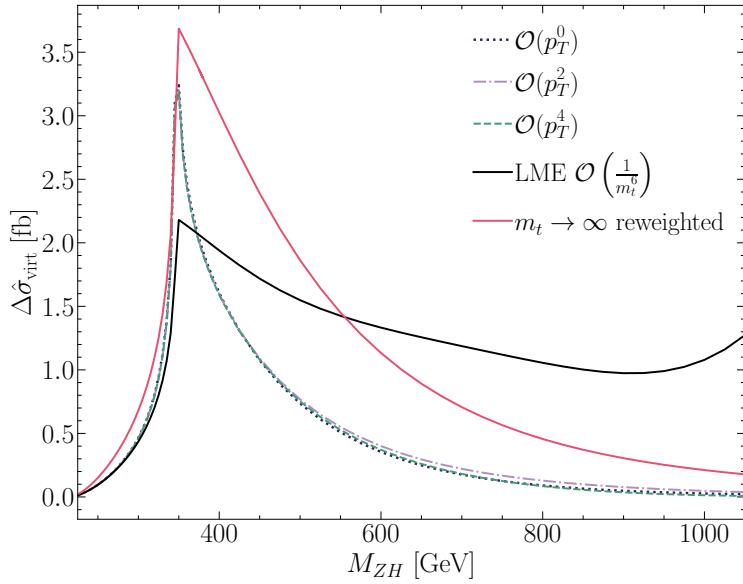

Figure 4.5. $\Delta\hat{\sigma}_{\text{virt}}$ defined by eq.(4.37), shown as a function of M_{ZH} . The various orders of the p_T -expansion are plotted as dashed lines, while the black and red continuous lines stand for the LME and reweighted $m_t \rightarrow \infty$ results, respectively. This plot has been already published in [173].

parts of the matrix elements the best results available, i.e. both $\mathcal{A}^{(0)}$ were used and the double-triangle contribution are evaluated exactly, while for $\mathcal{A}^{(1)}$ we use the various orders in the p_T -expansion. For comparison, the results are shown were $\mathcal{A}^{(1)}$ is replaced by the one computed in LME up to $\mathcal{O}(1/m_t^6)$ (full black line), which as mentioned before is valid up to $M_{ZhH} < 2m_t$. We observe that within the validity of the LME our results agree well with it. Furthermore, the results in the infinite top mass limit reweighted by the full amplitudes squared can be seen as the full red line in the plot, corresponding to the approach of ref.[180], keeping though the double triangle contribution in full top mass dependence. Differently from the LME line, the $m_t \rightarrow \infty$ reweighted one shows a behaviour, for $M_{Zh} \gtrsim 400$ GeV, similar to the behaviour of the p_T lines. Still, the difference between the reweighted result and the p_T -expanded ones is significant. The p_T -expanded results show very good convergence. The zero order in our expansion agrees extremely well with the higher orders in the expansion, and all the three results are very close up to $M_{Zh} \sim 500$ GeV.

The calculation of the virtual two-loop corrections to the $gg \rightarrow Zh$ is done using exact results for the triangle and double-triangle topologies, and in the p_T -expansion for the box one. The result of the calculation showed that we get the exact same MI's that was found for Higgs pair production [172] , mostly these MI's are expressed in terms of generalised harmonic polylogarithms with the exception of two elliptic integrals. Using the LO calculation, we have shown the validity of the p_T -expansion covering the invariant mass interval $M_{Zh} \lesssim 750$ GeV which covers $\sim 98\%$ of the total phase space for 13 – 14

TeV energies.

The p_T -expansion agrees with per mill level with the numerical results found in [199]. However, it allows for fast computation of the amplitude with circa one second per phase space point using a modern laptop with mid-range specifications. Additionally, the integration over the \hat{t} variable in eq.(4.37) converges very well. The flexibility of our analytic results, an application to beyond-the-Standard Model is certainly possible.

Finally, it should be noted that this calculation complements nicely the results obtained in ref.[191] using a high-energy expansion, that according to the authors provides precise results for $p_T \gtrsim 200$ GeV. The merging of the two analyses is going to provide a result that covers the whole phase space, can be easily implemented into a Monte Carlo code using v which is currently a work in progress in [Cite the new paper here-later](#)

Part II

Higgs Pair at Hadron Colliders

5 Overview of Higgs pair production at colliders

The determination of the shape of the Higgs potential is an essential part of the LHC physics programme. Unlike the determination of most properties of the Higgs and its couplings to heavy particles, the light Yukawa and Higgs-self couplings are exceptionally hard to probe. This is particularly evident from the conclusion of ???. When we have seen that the effectiveness of the utilisation of single Higgs signals in order to probe the Higgs trilinear coupling is challenged with the fact that other weakly constrained operators also affect these signals. Thus, Higgs pair production remains as the only direct way to access this elusive interaction.

The production of Higgs in pairs has roughly 10^{-4} the signal of producing a single Higgs at the LHC. The Higgs pair production with Higgs pair decays considered have a cross-section of $\sim 1\text{fb}$, in the SM. This would make it inaccessible from Run-II or Run-III data, but should be accessed using the whole luminosity of the HL-LHC [63, 202, 203]. As for the quartic coupling, which would require NLO corrections to Higgs pair, which are currently unknown, or triple Higgs production, both of which are beyond the sensitivity of the LHC [204]. The measurement potentials for the light Yukawa couplings shall be discussed in the Next chapter. The main advantages for Higgs pair production in determining the Higgs trilinear self-coupling comes from the dependence of the cross-section of λ_3 at the LO level, as well as the fact that the rest of SMEFT operators entering in this process (see eq (3.11)) can be strongly constraint from other processes, breaking any potential correlations that might appear between them and the trilinear coupling using only di-Higgs data. However, the inclusion of light quark Yukawa couplings modifiers e.g. $C_{u\phi}$ and $C_{d\phi}$ would complicate things as we shall see in [chapter 6](#).

This chapter will start by reviewing the theoretical status of the dominant process for Higgs pair production, the gluon fusion, in [section 5.1](#). Then, the other subdominant channels will be briefly reviewed in [section 5.2](#). I will afterwards overview the experimental efforts in probing this rare yet fascinating processes in [section 5.3](#). Finally, I will present in [section 5.4](#) a summary of the trilinear Higgs-self coupling constraints.

5.1 Higgs pair production by gluon fusion

The dominant process for Higgs pair production at the LHC (and hadron colliders in general) is the gluon gluon fusion (ggF) via a heavy quark loop Q , mainly the top and beauty quark, with the latter contributing only to about 1%, as shown in [Figure 5.1](#). This process is well-studied at leading order (LO) analytically [205–208]. The higher or-

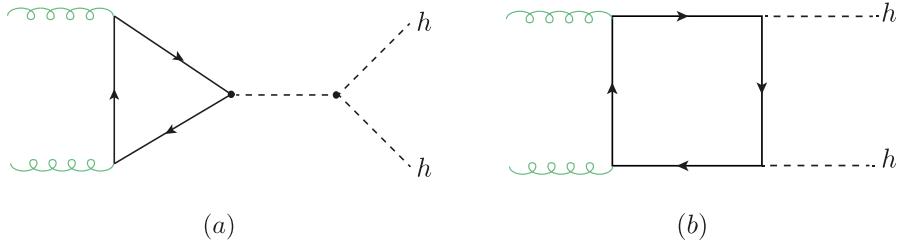

Figure 5.1. Feynman diagrams for the ggF process of Higgs pair production in the SM.

der computations are significantly more complicated to perform compared to the gluon fusion production of a single Higgs. This is due to the fact that multi-scale amplitudes at two-loops (and more) cannot be always computed analytically using the current computational techniques. The first attempt to compute the NLO corrections to di-Higgs were via the infinite top limit (HTL/LME) approximation [110, 180, 209] and implemented in `HPAIR`. These corrections were found to be large, with a K-factor of ~ 2 . This prompted more calculations with inclusion of top mass effects [210–214], which improved the stability of the LME expansion as well as corrected the cross-section by $\sim 10\%$. In addition, the threshold resummation effects of the LME has been included in [215]. This approach, however, is not sufficient to produce corrections to the differential cross-section, as the LME fails for $m_{hh}^2/4m_t^2 \lesssim 1$. Using numerical evaluation of the two-loop integrals, it is possible to obtain exact results with full top mass dependence, see refs. [216–218]. But this comes at the cost of computational power required to evaluate the cross-section. Hence, approximation methods were imperative in obtaining more flexible results for use at simulations and BSM Higgs pair production predictions. These approximations methods are analogous, and sometimes connected to the ones used for Zh production discussed in chapter 4. This includes, small final particle transverse momentum [172], and high energy (HE) expansions [219?]. In addition to a method developed in refs. [220, 221] which considers both \hat{s}, \hat{t} and m_t as large quantities while keeping the Higgs mass as small one. This method has a wide coverage of the m_{hh} spectrum. The use of Padé approximation to improve the p_T -expanded amplitude coverage as well as to obtain a description for the three-loop (NNLO) form factors was demonstrated in [222]. The NNLO cross section with top mass effects has been computed numerically in [223] and also at differential level [224], and analytically only in the LME [225]. Also, NLO+NNL analytic results have been obtained by [226]. Parton shower matching for NLO Higgs pair production has been computed in [227, 228], which was essential for the `POWHEG` implementation for di-Higgs, with NLO corrections computed from a grid has been made available by [157, 228, 229]. Figure 5.2 shows the Higgs pair virtual partonic cross-section defined in eq.(4.37) vs the p_T and HE expansions bridged using Padé approximants [add ref.](#)

Moreover, the NLO Higgs pair production with SMEFT operators is available in **SMEFTatNLO** mode [230] for **MadGraph**. Calculation of LO in addition to Higher order corrections to Higgs pair production in EFT, MSSM and composite Higgs models can be found in [148, 154, 231–233].

Figure 5.2. Feynman diagrams for the ggF process of Higgs pair production in the SM.

The NNLO correction were used according to the Higgs cross section working group recommended values [234, 235]:

$$K = \frac{\sigma_{NNLO}}{\sigma_{LO}}, \quad K_{14\text{TeV}} \approx 1.71. \quad (5.1)$$

5.1.1 Theoretical uncertainties

There are four main sources of theoretical uncertainties for Higgs pair production:

1. Scale uncertainty: coming form the arbitrariness of scales choice.
2. PDF uncertainties : coming form the uncertainty in the PDF fitting and model.
3. α_s running uncertainty: originating from the initial value (i.e. $\alpha_s(M_Z)$).
4. Top mass renormalisation scheme, which involves m_t appearing in the loop propagators and in the top Yukawa.

The computation of the uncertainties is described in [236, 237]. for PDF and α_s uncertainties. In order to calculate the scale uncertainties, the cross-section was computed with different μ_R and μ_F values ranging between:

$$\frac{M_{hh}}{4} \leq \mu_R/\mu_F \leq M_{hh} \quad (5.2)$$

As for the m_t renormalisation uncertainty, one uses the $\overline{\text{MS}}$ running of the top mass formula at N³LO [238]

$$\overline{m}_t(m_t^{pole}) = m_t^{pole} \left(1 + \frac{4}{3\pi} \alpha_s(m_t^{pole}) + 10.9 \frac{\alpha_s^2(m_t^{pole})}{\pi^2} + 107.11 \frac{\alpha_s^3(m_t^{pole})}{\pi^3} \right)^{-3} \quad (5.3)$$

The total 14 TeV ggF hh , cross-section at different orders in computation with its uncertainties are shown in Table 5.1, which indicates that the uncertainties are dominated by the m_t renormalisation scheme of $\sim -18\%$ uncertainty in the lower envelope. This is significant part of the uncertainty budget and needs to be resolved by including N³LO corrections to ggF hh , such corrections are available in the HTL [239, 240].

5.2 Other processes

Like the single Higgs production at hadron colliders, the production of Higgs pairs has the same subdominant channels VBF, di-Higgsstrahlung Vhh and associates production of Higgs pair with tops $t\bar{h}h/tjhh$. Their cross-sections and uncertainties at 14 TeV are shown in the table, while in Figure 5.3 their cross-sections as a function of the centre-of-mass energy \sqrt{s} is shown [242].

	σ [fb]	Scale [fb]	PDF+ α_s [fb]	Total [fb]
SM HEFT (LO)	18.10	—	—	—
SM running mass (LO)	16.96	—	—	—
SM (LO)	21.45	+4.29 -3.43	± 1.46	+4.53 -3.73
SM (NLO) [241]	33.89	+6.17 -4.98	+2.37 -2.01	+6.61 -5.37
SM (NNLO) [223]	36.69	+0.77 -1.83	± 1.10	+1.66 -6.43 (incl. m_t uncertainty [238])

Table 5.1. Gluon fusion (ggF) Higgs pair production cross-section at 14 TeV with theoretical uncertainties, the HTL/LME is computed using (SM HEFT), top running mass, LO, NLO and NNLO QCD corrections. The NLO and NNLO results are taken from the references cited in the table. The LO results are computed via a FORTRAN code.

5.2.1 VBF hh

Vector boson fusion hh production has the second largest cross-section after ggF hh , which is calculated up to N³LO [241, 243, 244] inclusively and differentially at NNLO [245]. The dominant diagrams are analigious to the single Higgs VBF, which involve the W/Z bosons exchanged in the t -channel. The process has the same topology as the -off shell-single Higgs VBF, with the off-shell Higgs giving two final states ones via the trilinear self-coupling.

5.2.2 Di-Higgsstrahlung

The associated production of Higgs pair with W and Z bosons has a small cross-section compared to ggF and VBF, this process is known up to NNLO QCD accuracy, which includes the gluon-fusion component in the full computation [246? , 247].

5.2.3 Associated Higgs pair production with t -quarks

Sometimes called the di-Higgs bremsstrahlung off top quarks [242], this channel has a steeper dependence on \sqrt{s} than the single Higgs bremsstrahlung $t\bar{t}h$. One can see, for example, from Figure 5.3 that its cross-section becomes at roughly the same values as the VBF's. Only NLO computations for this channels have been carried out [248].

All of the three channels have a relatively small NLO correction, compared to gluon fusion. Which ranges from 10-30%.

5.3 Experimental overview for Higgs pair production

5.4 Summary

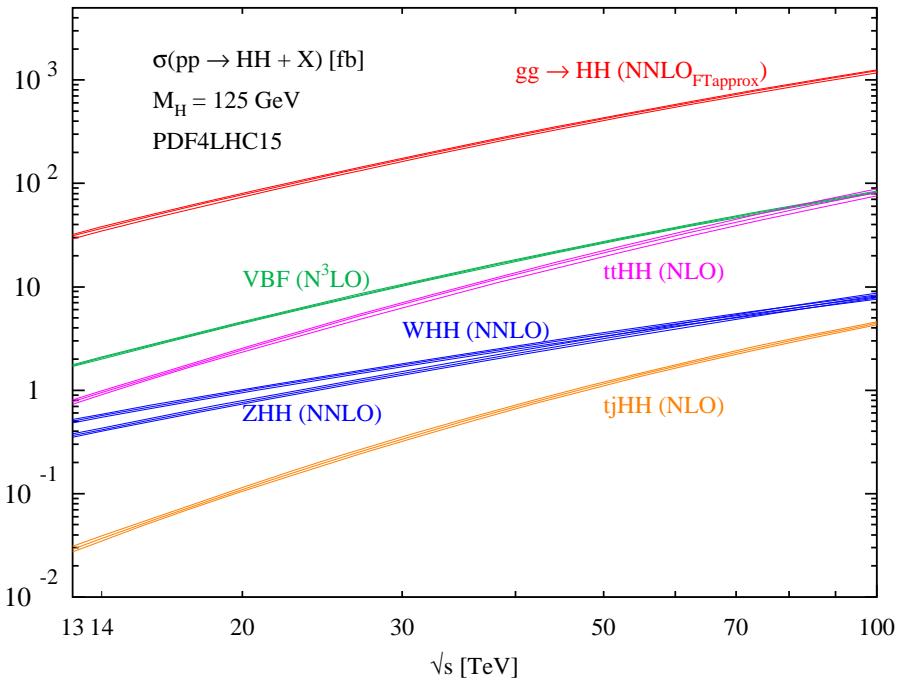

Figure 5.3. The cross-section of all di-Higgs processes at the highest available perturbation order as a function of centre-of-mass energy \sqrt{s} . The bands show the uncertainties without the top-mass renormalisation scheme. This plot is taken from [242]

6 Optimised search for Higgs pair via Interpretable machine learning

6.1 Introduction

The primary objectives of this work are as follows:

- We show some well motivated BSM scenarios where light-quark Yukawas can be enhanced simultaneously with the Higgs trilinear coupling.
- We perform an interpretable machine learning analysis based on boosted decision trees and Shapley values, a measure derived from Coalition Game Theory to extract signal significance to get a better handle on the measurement of light-quark Yukawas.
- We perform simultaneous fits for several combinations of light-quark Yukawa couplings and the Higgs trilinear coupling.

We show in ?? the relevant EFT operators for the di-Higgs processes, discuss flavor bounds and minimal flavor violation (MFV). Then we introduce in ?? the concept of aligned flavor violation (AFV), and various "concrete" examples realising large enhancement to light yukawa while evading flavor bounds. We then study the leading contributing channels with simulation details explained in section 6.2. Further we discuss in section 6.3 the multivariate analysis and interpretable machine learning approach we adopt. We present prospected results in section 6.4 at the HL-LHC and FCC. In section 6.5 we summarize our main findings.

In the general framework of SMEFT, additional assumptions on UV-motivated flavor structure avoids stringent low energy FCNC and EDM bounds, making collider probe on the Yukawa and related Wilson coefficients competitive and relevant. See a recent overview of Yukawa coupling bounds from flavor and collider Higgs data, in the SMEFT framework given certain flavor structure. [249]

The single Higgs production and decay channels as measured currently already provide indirect bounds on the light quark Yukawa couplings from global fit. The main sensitivity comes from enhancement to the production when $q\bar{q}$ fusion of the Higgs become comparable to ggF channel when the corresponding light-quark Yukawa is sufficiently enhanced. Secondly, there is additional overall "dilution" factor from the modified Higgs total width, for a final state of a specific (non-"light-jet") decay channel. In the case of di-Higgs, the $q\bar{q}hh$ contact interaction become important for the di-Higgs production, and could become dominant production channel over the SM gluon fusion channel

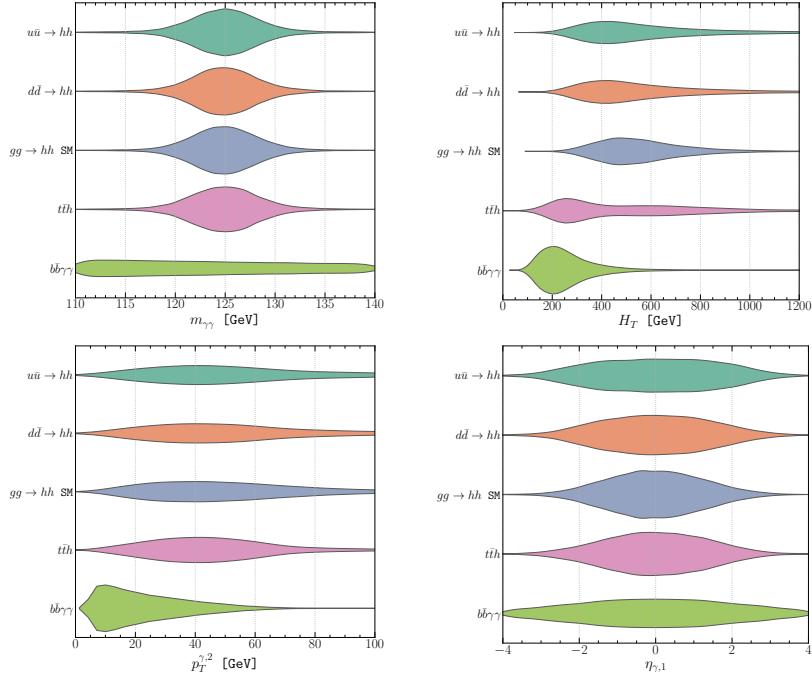

Figure 6.1. The .

through loop. The sensitivity thus achieved to the corresponding light-quark Yukawa in the SMEFT framework is better compared to that from single Higgs inclusive observable, and could even be competitive to single Higgs differential studies, as will be shown from our study.

6.1.1 Considerations of experimental constraints

For the 2HDM model, there are three main scenarios from the experimental searches point of view, in which one can obtain enhancements to light-quark Yukawa couplings. In the first scenario, the heavy Higgs H has a small mass $m_H < 2$ TeV. Experimental resonance searches rules out this scenario where the resonant Higgs pair production is enhanced significantly due to the decay $H \rightarrow hh$, as the trilinear Hhh coupling scales as [250]

$$g_{Hhh} \approx \frac{m_H^2}{v^2} \cos(\beta - \alpha). \quad (6.1)$$

In the second scenario, we have a heavier H but a large $Hq\bar{q}$ coupling. Here, the dijet resonance searches from $H \rightarrow jj$ decay, provides the strongest constraints. Lastly, when we consider a heavy H and $Hq\bar{q}$ not excluded by di-jet searches we lie within the EFT limit and non-resonant Higgs pair production discussed in this paper gives us the dominant constraints.

In the 2HDM with AFV or SFV, there is an interplay between light quark Yukawa

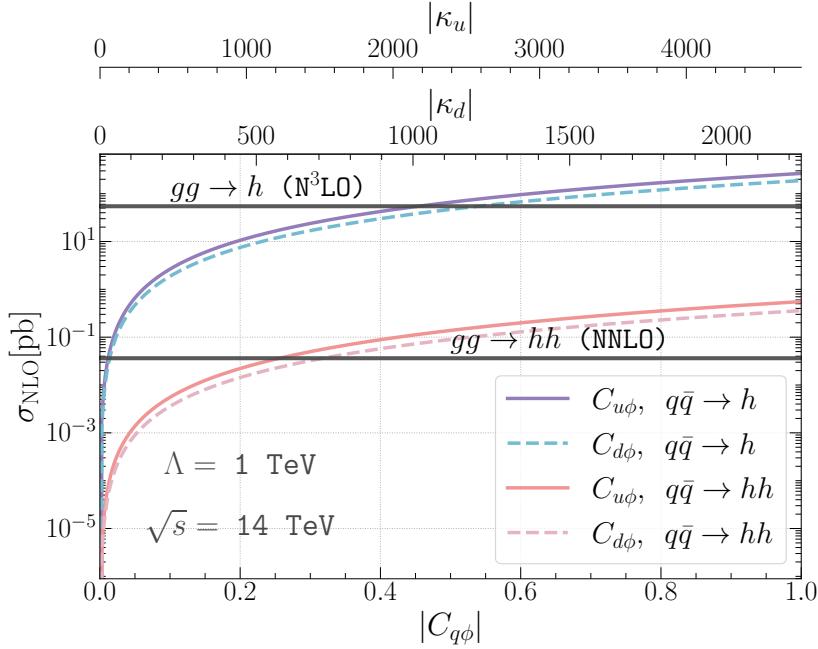

Figure 6.2. The production cross-section of single Higgs and di-Higgs at 14 TeV from the quark anti-quark annihilation $q\bar{q}A$ as a function of the Wilson coefficients $C_{u\phi}$ and $C_{d\phi}$ versus the SM gluon fusion cross-sections (the horizontal solid line for $gg \rightarrow h$ and the dashed-dotted one for $gg \rightarrow hh$). One can observe that for values of $C_{u\phi} = 0.22(0.43)$ and $C_{d\phi} = 0.26(0.47)$ the $q\bar{q}A$ channel becomes the dominant di-Higgs (single Higgs) production channel. The UV scale is set to $\Lambda = 1$ TeV.

and the Higgs trilinear self-coupling. This comes from the alignment parameters α and β , as we see in equations (??) and (??). For example, when the mass of H is allowed to be very large $m_H > 4$ TeV, enhancement to light-quark Yukawa couplings would be completely constrained from the bound on the Higgs self-coupling provided the 2HDM potential is tuned to avoid triviality and perturbativity bounds.

From the discussion in this section we see that several models are present in the literature that are able to accommodate for large deviations of the light-quark Yukawa couplings from their SM values while avoiding excessive contributions to FCNCs that are well measured and particularly limiting for models with additional flavour structures due to the implementation of AFV or SFV. The primary new physics deviation, complementary to direct searches, in the presented models will show up in the modification of the light quark Yukawa couplings. Armed with this knowledge, we motivate a study of how light-quark Yukawa couplings can be constrained at future experiments from Higgs pair production.

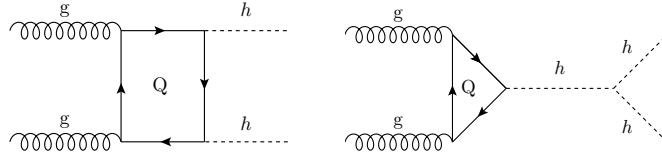

Figure 6.3. The cross-section of the ggF channel can be decomposed into three subprocesses based on its dependence on the trilinear coupling λ . The triangle topology depends on λ^2 , the box one does not depend on it and the interference amongst the latter two is linear in λ .

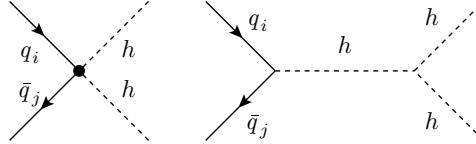

Figure 6.4. The dominant Feynman diagrams for the quark anti-quark annihilation ($q\bar{q}A$) production of Higgs pair, via the SMEFT operator $\mathcal{O}_{q\phi}$.

6.2 Events simulation for HL-LHC and FCC-hh

We consider the final state $b\bar{b}\gamma\gamma$, as this channel has the most potential for Higgs pair searches [203]. It has the “clean” $h \rightarrow \gamma\gamma$ decay, but also the other Higgs decay to b -quark pair is a channel with large branching ratio $\sim 58\%$ and b-tagging capabilities for ATLAS and CMS are continuously improving.

Channel	LO σ [fb]	NLO K -fact	6 ab^{-1} [#evt @ NLO]
y_b^2	0.0648	1.5	583
$y_b y_t$	-0.00829	1.9	-95
y_t^2	0.123	2.5	1,840
$Z h$	0.0827	1.3	645
$\sum b\bar{b}h$	0.262	-	2,970
$b\bar{b}\gamma\gamma$	12.9	1.5	116,000
$t\bar{t}h$	1.156	1.2	6,938

Table 6.1. SM cross-section for the main background processes at 14 TeV with 6 ab^{-1} data at the HL-LHC, and the number of events after the basic cuts as defined in Equation 6.3. For $b\bar{b}h$ production, the Higgs boson is decayed to a pair of photons. The total production of Higgs associated with $b\bar{b}$ is denoted by $\sum b\bar{b}h$ and is the sum of the top four channels.

To be able to study the effects of enhanced light-quark Yukawa couplings or Higgs trilinear coupling, we need to simulate events for HL-LHC and FCC-hh which we use to train a machine learning model to identify the signal from the background. We consider the $b\bar{b}h$, $t\bar{t}h$, $b\bar{b}\gamma\gamma$ processes as the main sources of background for the hh signal. For the $b\bar{b}h$ processes, the contributions proportional to y_b^2 , $y_b y_t$ and y_t^2 are simulated separately with y_b running effects. The details of the simulation can be found in Ref. [251]. The $Z h, Z \rightarrow b\bar{b}$ events are generated at leading order (LO), then scaled to NLO by K -

Channel	LO σ [fb]	K -fact.	Order	6 ab^{-1} [#evt @ order]
$hh_{\text{tri}}^{\text{ggF}}$	$7.288 \cdot 10^{-3}$	2.28		96
$hh_{\text{box}}^{\text{ggF}}$	0.054	1.98	NNLO	680
$hh_{\text{int}}^{\text{ggF}}$	-0.036	2.15		-460
$u\bar{u}\text{A}$ ($C_{d\phi} = 0.1$)	2.753	1.29	NLO	28
$d\bar{d}\text{A}$ ($C_{u\phi} = 0.1$)	4.270	1.30		43

Table 6.2. The LO cross-section for di-Higgs production at the HL-LHC for 6 ab^{-1} of data multiplied by the $hh \rightarrow b\bar{b}\gamma\gamma$ branching ratio, K -factors (taken from [156] for the gluon channels and [258] for the quark channels) and the number of events after the basic cuts for the separated gluon fusion (ggF) and quark annihilation ($q\bar{q}\text{A}$) at $\sqrt{s} = 14 \text{ TeV}$.

factors, defined as the ratio of higher order cross section over its LO counterpart. The K -factors were taken from $t\bar{t}h$ [252], $b\bar{b}\gamma\gamma$ [253], Zh [254] and the remaining part of the $b\bar{b}h$ processes from [255]. The Higgs particles are further decayed to $\gamma\gamma$ following the Higgs cross-section working group recommendations [153]. The parton-level results are showered using **Pythia 8.3** [256] and a detector simulation is done using **Delphes 3** [257]. To be inclusive and to explore the capabilities and importance of the full detector coverage, no generator-level cuts were applied on these processes except for the $b\bar{b}\gamma\gamma$ processes to avoid divergences. These minimal generator-level cuts for $b\bar{b}\gamma\gamma$ are

$$\begin{aligned} Xp_T^b &> 20 \text{ GeV}, \\ \text{generator level cuts: } &\eta_\gamma < 4.2, \Delta R_{b\gamma} > 0.2, \\ &100 < m_{\gamma\gamma} (\text{GeV}) < 150. \end{aligned} \quad (6.2)$$

Here Xp_T implies a minimum p_T cut for at least one b -jet. After the showering and detector simulation, further basic selection cuts were applied to select events with

$$\begin{aligned} \text{basic cuts: } &n_{\text{eff}}^{b\text{jet}} \geq 1, n_{\text{eff}}^{\gamma\text{jet}} \geq 2, \\ &p_T^{b\text{jet}} > 30 \text{ GeV}, p_T^{\gamma\text{jet}} > 5 \text{ GeV}, \\ &\eta_{b\text{jet}, \gamma\text{jet}} < 4, 110 \text{ GeV} < m_{\gamma_1\gamma_2} < 140 \text{ GeV}, \end{aligned} \quad (6.3)$$

and $n_{\text{eff}}^{b/\gamma\text{jet}}$ representing the number of b/γ -jets that pass the basic selection. The cross-section, K -factors, number of events with 6ab^{-1} luminosity at 14 TeV are given in Table 6.1.

While the backgrounds are generated using **MadGraph_aMC@NLO** [259], the hh signal is separated into two main channels. The first is the gluon-fusion (ggF) channel which is the dominant channel in the SM and which can be further decomposed into three subprocesses based on their dependence on the Higgs trilinear self-interaction, λ , as seen in Figure 6.3. Amongst these subprocesses, the first is the amplitude squared of the contribution from the triangle diagram. It is proportional to λ^2 . The second is the squared amplitude of the contribution from the box diagram that does not depend on

the trilinear coupling. The third is the contribution from the interference between the triangle and box diagrams, which is proportional to λ . Using this separation allows us to remove the dependence of the total K -factor for hh production on rescaling of the trilinear Higgs coupling [228]. The individual K -factors for each of the subprocesses are independent of the rescaling of the trilinear Higgs coupling making our analysis computationally much simpler. The ggF process is generated using the HH production program implemented in **POWHEG** [157, 228, 229], which has been modified to separate the individual contributions from the three diagrams. The cross-section for these individual contributions and the corresponding K -factors can be found in [Table 6.2](#).

The other main process, the quark anti-quark annihilation ($q\bar{q}A$), is strongly suppressed in the SM for first generation quarks since the SM Yukawa couplings are proportional to the mass of the considered quark flavour. However, since this channel is a tree-level process, with sufficient large enhancement factors of the light quark Yukawa coupling, it becomes dominant as shown in [Figure 6.2](#). The $q\bar{q}A$ cross section scales like $\tilde{C}_{q\phi}^2/\Lambda^4$, while the gluon fusion production cross-section remains almost unchanged. Therefore, for constraining enhancements of the light-quark Yukawa, we consider this channel as the signal and the ggF channel as part of the background. The $q\bar{q}A$ process is generated with **MadGraph_aMC@NLO** with a UFO model created with **FeynRules** [260]. Samples for both up- and down-quark initiated $q\bar{q}A$ processes is generated. For all the hh signals, the samples are generated at LO and later scaled by the NLO K -factors given in [Table 6.2](#). The K -factors are obtained from ref. [154] for the gluon fusion process in EFT and adapted from [261–263] as described in [258] for the $q\bar{q}A$ channel. Moreover, the two Higgs bosons are decayed to $b\bar{b}$ and $\gamma\gamma$ respectively, with **Pythia 8.3** and then showered. The same detector simulation and basic cuts as for the background are then performed. In addition, the same sets of parton distribution function (`NNPDF31_nlo_as_0118_nf_4`) are used for the signal and the background, implemented via **LHAPDF** [264]. The calculation of the Higgs full width and branching ratios is done using a modified version of **Hdecay** [265, 266] to include the new SMEFT operators $\mathcal{O}_{q\phi}$. It should be noted, that in both di-Higgs production and decay calculation, the light-quark masses are set to zero. However, when converting between SMEFT and κ -formalism, the $\overline{\text{MS}}$ quark masses are used, in accordance to the PDG.

For FCC-hh, almost everything is done similarly after setting the energy to 100 TeV and the luminosity to 30 ab^{-1} . Since we do not have all K -factors available at a collider energy of 100 TeV we rescaled the LO samples by the same ones as for HL-LHC. We note that we explicitly checked that at least within the SM, for Higgs pair production via gluon fusion the difference is of $\mathcal{O}(1\%)$ [212] and hence small.

6.3 Exploring higher dimensional kinematic distributions

After detector simulation and jet definition, we have a final state of two photon jets and at least one b -jet, where the two photons reconstruct back to a real scalar Higgs mass for all the $b\bar{b}h$ channels. We first define and evaluate a comprehensive set of kinematic observables as the following:

- $p_T^{b_1}$, $p_T^{b_2}$, $p_T^{\gamma_1}$, $p_T^{\gamma\gamma}$,
- $\eta_{b_{j1}}$, $\eta_{b_{j2}}$, η_{γ_1} , $\eta_{\gamma\gamma}$,
- n_{bjet} , n_{jet} , $\Delta R_{\min}^{b\gamma}$, $\Delta\varphi_{\min}^{bb}$,
- $m_{\gamma\gamma}$, m_{bb} , $m_{b_1 h}$, $m_{b\bar{b}h}$, H_T .

$p_T^{b/\gamma_{1,2}}$ and $\eta^{b/\gamma_{1,2}}$ are the p_T and rapidity for the tagged leading and sub-leading b/γ -jets (in our definition the subleading b -jet could be a null four-vector since we require one b -jet inclusive), n_{bj} is the number of tagged and passed b -jets. $\Delta R_{\min}^{b\gamma}$ and $\Delta\varphi_{\min}^{bb}$ are the minimum R -distance and φ -angle between a tagged b -jet and a photon jet. The remaining variables are the invariant masses and H_T is the scalar sum of the transverse mass of the system. We shall show in what follows, that it is not necessary to be very selective about the kinematic variables one chooses to use in the analysis. What is necessary is that all possibly useful kinematic variables are included. As can be seen from the list above, some of the variables seem to be interdependent and, probably, highly correlated. The beauty of using interpretable machine learning is that a hierarchy of importance for the variables will be built during the analysis using an over-complete basis of collider observables from which the most important ones can be chosen to fine tune the analysis.

6.3.1 Interpretable machine learning

Rule-based machine learning algorithms have for long been used as the gold standard for signal to background discrimination in a wide variety of particle physics analyses. They are known to outperform neural networks in terms of simplicity of implementation, computational resources required and accuracy in modelling the underlying distributions.¹ In addition, rule-based algorithms, such as decision trees, are more transparent as far as the signal vs. background separation is concerned. Placing emphasis on interpretability in multivariate analyses, we chose to work with Boosted Decision Trees (BDT). However, interpretability of a machine learning algorithm requires more than just a choice of an interpretable model. The conditions are:

- A variable set that is easily interpretable in terms of the dynamics being studied.
- A machine learning algorithm that is more transparent and not a complete black box.
- A method for interpreting the model and attribute variable importance to understand how the algorithm models the underlying distributions.

Choosing to work with BDTs just satisfies the second condition. We work with the BDT algorithm implemented in XGBoost [268], a publicly available scalable end-to-end boosting system for decision trees. We follow the normal procedures for training

¹Nevertheless, we tested a deep neural network built with Tensorflow [267] and found no improvement in the classification accuracy.

and testing the BDT with simulated data. To satisfy the first condition we chose to work with high level kinematic variables that are representative of the process instead of working with four-vectors. The disadvantage of working with kinematic variable is that a complete set cannot be defined for a particular process unlike the four-vectors associated with the process. So, in principle, a large number of kinematic variables can be formulated and used in a multivariate analysis. While the number is never too large for any implementation of BDTs, having a large set of variables clouds the understanding of which ones are important for orchestrating the signal separation from the background. This is where the third point listed above is important. Variable importance attribution is a way to “short-list” only those variable that play an important role in predictive power of the classification (or regression) problem. There are several measures of variable importance used in machine learning like Gini or permutation based measures [269, 270], local explanations with surrogate models [271] etc., to name a few. However, these suffer from inconsistencies or fail to provide a global explanation of the model [272].

To build a mathematically consistent procedure for variable importance attribution we use Shapley values [273] from Coalition Game Theory. Formulated by Shapley in the mid-20th century, Shapley values formulate an axiomatic prescription for fairly distributing the payoff of a game amongst the players in a n -player cooperative game. When applied to machine learning, Shapley values tell us how important the presence of a variable is in determining a certain category (like signal or background) when compared to its absence from the multivariate problem being addressed. The process naturally and mathematically lends itself to studying the correlations between different variables since all possible combinations of variables can be taken out of the game to check the outcome.² A more detailed discussion of the application of Shapley values to signal vs. background classification problems for particle physics can be found in Refs. [251, 275, 276]. In this work we follow the same basic procedure as discussed in Ref. [251]. The importance of a variable in determining the outcome of a classification will be quantified by the mean of the absolute Shapley value, $\overline{|S_v|}$, larger values signifying higher importance. We will use the SHAP (SHapley Additive exPlanations) [272] package implemented in python based on Shapley values calculated exactly using tree-explainers [277, 278].

6.4 The hh channel at future hadron colliders

We would like to study the bounds on three specific couplings in this work. The first one being the Higgs trilinear coupling quantified by C_ϕ defined in ?? and the other two being the deformation of the first-family SM Yukawa coupling to the up and down quark defined as $C_{u\phi}$ and $C_{d\phi}$ in ?? with $i = j = 1$. We will not consider modifications of the second generation of quarks as their effects in di-Higgs production would be suppressed by the small parton distribution functions and are hence expected to be more pronounced using other methods for constraining them. For ease of interpretation we will also present

²More clarity on Shapley values and interpretable machine learning in general, along with their application can be found in [Interpretable Machine Learning](#) by Christoph Molnar [274].

our results in terms of κ_λ , κ_u and κ_d which are simply the rescaling of the SM trilinear coupling and the light-quark Yukawa couplings of the up and down quarks, respectively.

In the BDT analysis we combine the $b\bar{b}h$, ($h \rightarrow \gamma\gamma$) and $t\bar{t}H$, ($h \rightarrow \gamma\gamma$) channels into one category calling it $Q\bar{Q}h$ while the other (continuum) background channel, $b\bar{b}\gamma\gamma$, is treated as a separate category. For any analysis involving C_ϕ , we need three separate categories for the triangle, box and interference terms of the ggF hh production which we shall refer to as $hh_{\text{tri}}^{\text{ggF}}$, $hh_{\text{box}}^{\text{ggF}}$ and $hh_{\text{int}}^{\text{ggF}}$, respectively. The $q\bar{q}A$ channels stands for two other categories, one each for probing the Wilson coefficients $C_{u\phi}$ and $C_{d\phi}$, respectively. However, the $q\bar{q}A$ channels are not the only channels sensitive to $C_{u\phi}$ and $C_{d\phi}$. In fact the decay $h \rightarrow \gamma\gamma$, the production of the Higgs in the ggF channel and the width of the Higgs are modified by the size of $C_{u\phi}$ and $C_{d\phi}$ [258]. Hence, these as well need to be taken into account. In what follows, we will refer to the two $q\bar{q}A$ channels as $u\bar{u}A$ and $d\bar{d}A$ explicitly.

As we progress through the analysis we study the modification of one, two and three Wilson coefficients at a time. To extract just C_ϕ from the data we need to perform a five channel classification (two signal and three background modes including the $hh_{\text{box}}^{\text{ggF}}$ contribution that is insensitive to modifications of C_ϕ). To extract either $C_{u\phi}$ or $C_{d\phi}$ we have to perform a four channel classification taking the ggF channel as a single background mode. To extract C_ϕ and one of $C_{u\phi}$ or $C_{d\phi}$ we need to perform a six channel classification. Lastly, to extract all three Wilson coefficients we will need a seven channel classification. All the codes and data necessary to reproduce the results we got from this interpretable machine learning framework are made available at a **Github** repository: <https://github.com/talismanbrandi/IML-diHiggs.git>.

To set the stage, we will define our measure of significance and how we estimate it. We first construct a confusion matrix from the predictions of the trained BDT. This is a $n \times n$ matrix, for n channels. The sum of the elements in the i^{th} row, $\sum_j N_{ij}$, gives the actual number of events produced in channel i that would be generated in a pseudo-experiment with the projected luminosity corresponding to the actual experiment. The sum of the j^{th} column, $\sum_i N_{ij}$, gives the number of events from channel j predicted (including correct classifications and misclassifications) by the BDT in this pseudo-experiment. Hence the (i, j) element of the matrix gives the number of events of the i^{th} class that is classified as belonging to the j^{th} class with $i \neq j$ signifying a misclassification. The significance of the j^{th} channel given by $S/\sqrt{S+B}$, S being signal and B being background, can be defined as

$$\mathcal{Z}_j = \frac{|N_{jj}|}{\sqrt{\sum_i N_{ij}}}, \quad (6.4)$$

where i is the row index and j is the column index.

The fact that machine learning algorithms can far outperform cut-and-count analyses is a bygone conclusion. Preliminary estimates of the HL-LHC reach for SM di-Higgs production can be found in [203] and range from 4σ to 4.5σ signal significance combining several channels and both the ATLAS and CMS measurements. The $b\bar{b}\gamma\gamma$ final state alone allows for a $\sim 2.7\sigma$ measurement. In [279] a more refined machine learning procedure using Bayesian Optimization has been suggested and it has been shown that,

indeed, the measurement of a di-Higgs signal can be further improved over preliminary estimates made by ATLAS and CMS using the $b\bar{b}\gamma\gamma$ final state alone. A sensitivity of about 5σ can be achieved using their procedure with the caveat that they use S/\sqrt{B} as the definition of significance with very low number of signal and background events. As an exercise we repeated the BDT analysis with our framework and estimated a $\sim 3.4\sigma$ signal significance for SM di-Higgs production, which is similar to the estimate made in [279] without using any optimization.

A better portrayal of the advantages gained by using a multivariate analysis can be made by comparing the constraints set on $C_{u\phi}$, or κ_u , and $C_{d\phi}$, or κ_d , from a cut-and-count (CC) analysis and a multivariate (MV) analysis allowing for the variation of only one Wilson coefficient at a time. The projected 1σ bounds at HL-LHC for 6 ab^{-1} of luminosity for a CC are given in [258] and compare to our results as follows

$$\begin{aligned} C_{u\phi}^{MV}(\kappa_u^{MV}) &= [-0.09, 0.10] \quad([-466, 454]), & C_{u\phi}^{CC}(\kappa_u^{CC}) &= [-0.18, 0.17] \quad([-841, 820]), \\ C_{d\phi}^{MV}(\kappa_d^{MV}) &= [-0.16, 0.16] \quad([-360, 360]), & C_{d\phi}^{CC}(\kappa_d^{CC}) &= [-0.18, 0.18] \quad([-405, 405]). \end{aligned} \tag{6.5}$$

From this we clearly see a factor of ~ 2 improvement in the bounds on $C_{u\phi}$ and $\mathcal{O}(10\%)$ improvement in the determination of $C_{d\phi}$. The projected bounds on these operators at FCC-hh with 30 ab^{-1} of data using our framework are

$$\begin{aligned} C_{u\phi}^{MV}(\kappa_u^{MV}) &= [-0.012, 0.011] \quad([-57.8, 54.7]), \\ C_{d\phi}^{MV}(\kappa_d^{MV}) &= [-0.012, 0.012] \quad([-26.3, 28.4]). \end{aligned} \tag{6.6}$$

These projected bounds for FCC-hh are an order of magnitude better than those for HL-LHC. In addition, the bounds on $C_{u\phi}$ and $C_{d\phi}$ are numerically the same displaying a much greater improvement in the bounds on $C_{d\phi}$ than on $C_{u\phi}$ at the higher energy collider.

6.4.1 Constraints on C_ϕ at the HL-LHC and FCC-hh

First, we will show the projections of the limits that can be set on C_ϕ (or equivalently, κ_λ) from HL-LHC and FCC-hh. In Table 6.3 we provide the output of the BDT classification for 6 ab^{-1} of data collected at HL-LHC and in Table 6.4 we provide the same for 30 ab^{-1} of data at FCC-hh. It can be seen from these matrices that while the $b\bar{b}\gamma\gamma$ QCD-QED channel is the dominant background, the BDT performs better in separating it from the signal channels than separating $Q\bar{Q}h$. This is due to the kinematic similarities between the signal and the $Q\bar{Q}h$ background.

In Figure 6.5 we present the constraints on C_ϕ (or κ_λ) that can be set from HL-LHC in the left panel and FCC-hh in the right panel. The $hh_{\text{box}}^{\text{ggF}}$ topology is not modified by C_ϕ and serves as a background to the measurement of C_ϕ . We separate the constraints from the $hh_{\text{tri}}^{\text{ggF}}$, which is quadratic in C_ϕ from the $hh_{\text{int}}^{\text{ggF}}$ which is linear in C_ϕ . The combination of the two is given by the red dot-dashed line and is asymmetric around

Predicted no. of events at HL-LHC							
Actual no. of events	Channel	$hh_{\text{tri}}^{\text{ggF}}$	$hh_{\text{tri}}^{\text{ggF}}$	$hh_{\text{box}}^{\text{ggF}}$	$Q\bar{Q}h$	$b\bar{b}\gamma\gamma$	total
	$hh_{\text{tri}}^{\text{ggF}}$	28	14	18	38	10	108
	$hh_{\text{int}}^{\text{ggF}}$	89	80	129	178	41	517
	$hh_{\text{box}}^{\text{ggF}}$	77	105	266	265	50	763

	\mathcal{Z}_j	10.95	31.22	111.1	737.7	4,743	

Table 6.4. Trained BDT classification (confusion matrix) of the five channel used to extract constraints on C_ϕ (or κ_λ) at FCC-hh with 30 ab^{-1} luminosity, assuming SM signal injection. The right-most column gives the total number of events expected in each channel in the SM and the bottom-most row gives the signal significance.

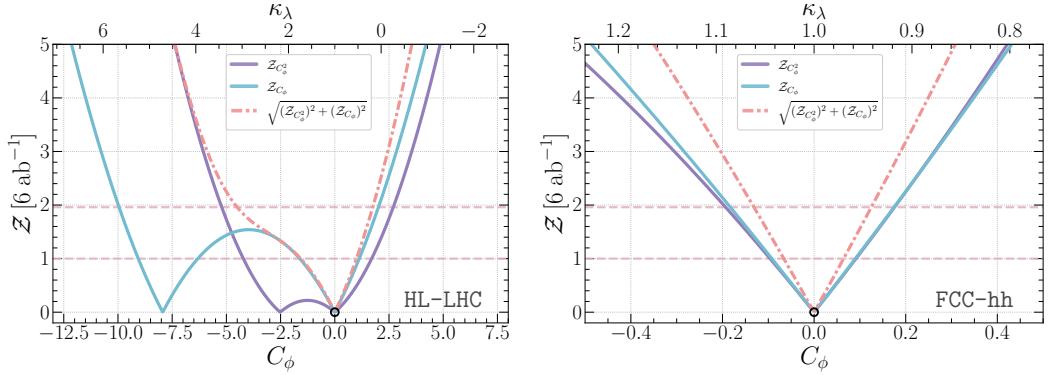

Figure 6.5. Bounds on C_ϕ (or κ_λ) at the HL-LHC (left panel) and the FCC-hh (right panel). The solid blue lines are the constraints coming from the $hh_{\text{int}}^{\text{ggF}}$ contribution which scales linearly with the modified coupling and the solid purple line is that from the $hh_{\text{tri}}^{\text{ggF}}$ contribution that scales quadratically with the modified coupling. The red dashed line is the combination of the quadratic and linear channel. The horizontal light red dashed lines marks the 68% and 95% confidence intervals.

the best fit point, for SM signal injection, $C_\phi = 0$ ($\kappa_\lambda = 1$). The projected 1σ bound on C_ϕ is $[-1.57, 1.00]$ at HL-LHC. There is a vast improvement projected for the FCC-hh which is not only due to increased luminosity but also due to the measurement being at a higher energy. The projected 1σ bound is $C_\phi = [-0.066, 0.064]$. The latter corresponds to a 3% bound on κ_λ .

6.4.2 Two and three parameter constraints on C_ϕ , $C_{u\phi}$ and $C_{d\phi}$

The primary focus of this work is to move beyond just looking at constraints on C_ϕ from di-Higgs production and to shed light on how simultaneous modifications of the light-quark Yukawa couplings due to non-zero contributions from $C_{u\phi}$ and $C_{d\phi}$ can change the constraints on C_ϕ . The modifications of the light-quark Yukawa couplings manifest themselves in two different ways. Firstly, non-zero $C_{u\phi}$ and $C_{d\phi}$ open up the $q\bar{q} \rightarrow hh$ production mode through a point interaction (see Figure 6.4) thus changing the production cross-section of the di-Higgs channel. This increase in the production cross-section sets the tightest constraints on $C_{u\phi}$ and $C_{d\phi}$ from di-Higgs production. Secondly, the modification of the light-quark Yukawa couplings also modify the branching fraction of $h \rightarrow \gamma\gamma$ and the width of the Higgs. The latter modifies the channels that are also sensitive to C_ϕ , thus modifying the constraints that can be set on C_ϕ from future measurements. Such constraints are the subdominant ones on $C_{u\phi}$ and $C_{d\phi}$ but they are necessary for a holistic picture.

In the two parameter fits, we consider three possible scenarios. Firstly, one can assume that the trilinear Higgs coupling is not modified and only the light-quark Yukawa couplings are. Two other possibilities are the simultaneous modification of the C_ϕ and one of $C_{u\phi}$ and $C_{d\phi}$. These are the three constraints that we show in Figure 6.6. As

Operators	$C_{u\phi}$	$C_{d\phi}$	C_ϕ		κ_u	κ_d	κ_λ
HL-LHC 14 TeV 6 ab $^{-1}$							
\mathcal{O}_ϕ	—	—	[-1.57, 1.00]		—	—	[0.53, 1.73]

All	[-0.009, 0.010]	[-0.009, 0.010]	[-0.105, 0.023]		[-47, 44]	[-21, 21]	[0.99, 1.05]

Table 6.5. The 1σ bounds on $C_{u\phi}$, $C_{d\phi}$ and C_ϕ from one-, two- and three-parameter fits for HL-LHC with 6ab^{-1} of data and FCC-hh with 30ab^{-1} of data. The corresponding bounds on the rescaling of the effective couplings, κ_u , κ_d and κ_λ are presented on the right side of the table.

before, the constraints have been obtained by training the BDT to separate the relevant signal channels from the background, the signal used being the one corresponding to the pair of Wilson coefficients that we intend to constrain. The confusion matrices for all the three cases can be found in the [Github](#) repository for this analysis. The left panels of Figure 6.6 show the projected constraints for HL-LHC and right panels for the FCC-hh.

Comparing with the constraints on C_ϕ given in subsection 6.4.1 and Figure 6.5, it can be seen from the top and middle left panels of Figure 6.6 that, indeed, the constraints on C_ϕ are diluted when the light-quark Yukawa couplings are allowed to vary. This effect is somewhat more prominent for $C_{d\phi}$ than for $C_{u\phi}$ and stems from the fact that away from $C_{u\phi,d\phi} = 0$ larger negative values of C_ϕ are allowed by the crescent shaped curves in Figure 6.6. For $C_{d\phi}$ vs. C_ϕ the 3σ region is unbounded in the domain $|C_{d\phi}| \gtrsim 0.6$. The bounds on $C_{u\phi}$ and $C_{d\phi}$ from the fit with two-parameters including C_ϕ remain the same as the bounds on these Wilson coefficient from the single parameter $C_{u\phi,d\phi}$ fits. We summarize the results in Table 6.5.

It should be noted that the two-parameter fit for $C_{u\phi}$ and $C_{d\phi}$ provide a stronger bound on the two parameters than the fit done individually. While this might be a bit counter-intuitive considering constraints from fits tend to deteriorate with the increasing number of parameters, we found that is not the case here. The reason is that the two-parameter fit is performed with the predictions made by the BDT trained with simulated events for both $u\bar{u}A$ and $d\bar{d}A$. Between these two channels, each form the background for the other when separating them through a confusion matrix. Since the training also give the proportion of mistagged events, both the signal and the backgrounds are modified by

the Wilson coefficients leading to a greater deformation of the likelihood in a favourable direction such that the constraints on the Wilson coefficients in the two-parameter fit is better than for the case in which they were separated from other $b\bar{b}\gamma\gamma$ backgrounds individually.

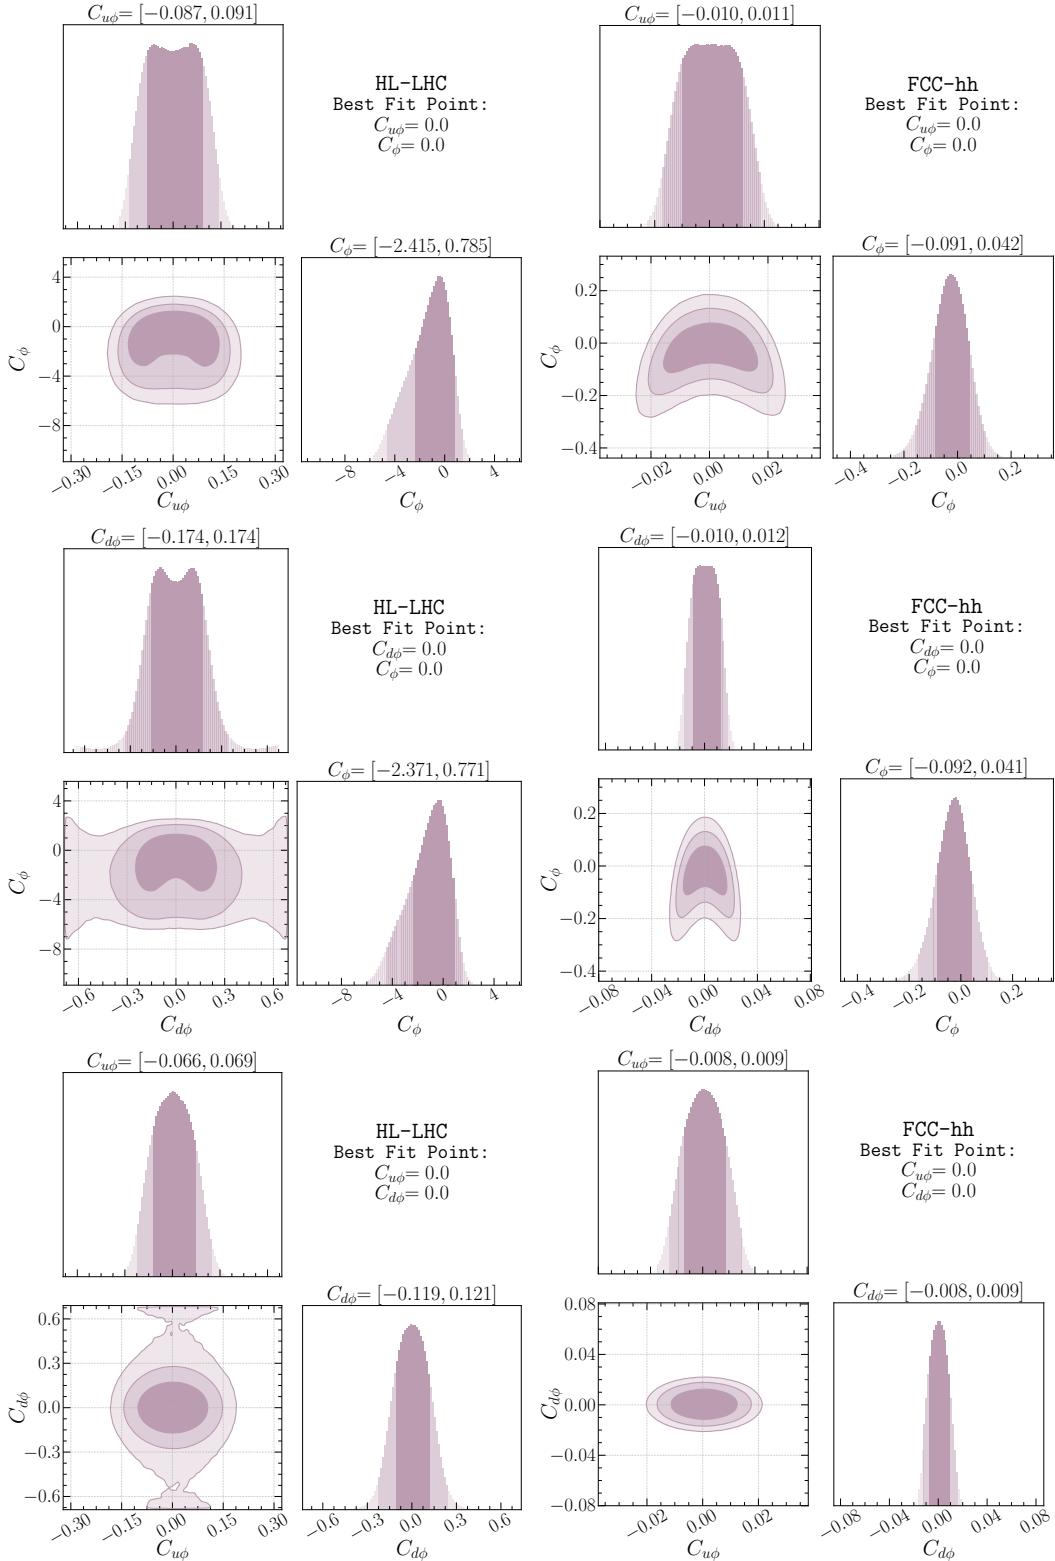

Figure 6.6. Constraints on pairs of Wilson coefficients for C_ϕ , $C_{u\phi}$ and $C_{d\phi}$. The panels of the left are for HL-LHC with 6 ab^{-1} of luminosity and the ones on the right are for FCC-hh with 30 ab^{-1} of luminosity.

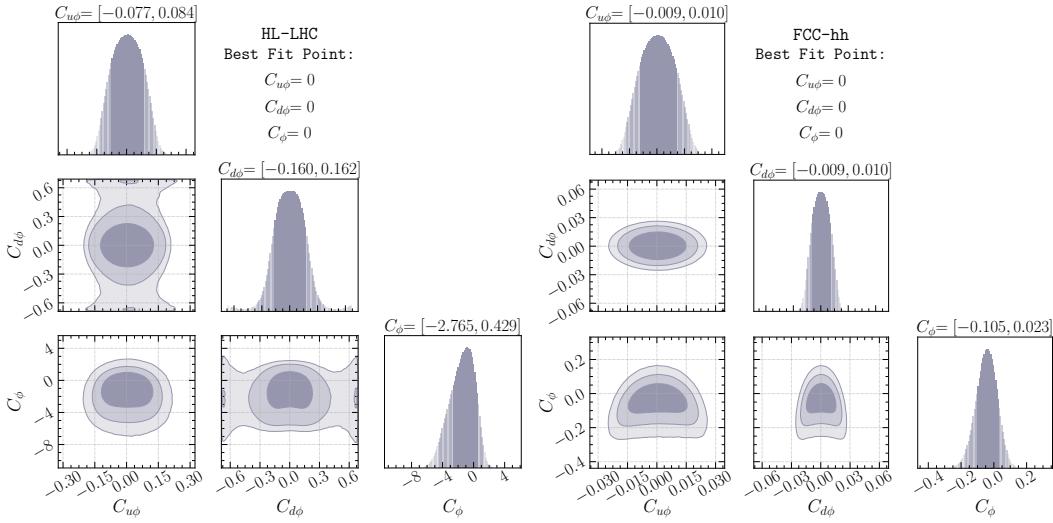

Figure 6.7. Three parameter fits with $C_{u\phi}$, $C_{d\phi}$ and C_ϕ , 6ab^{-1} of luminosity at 14 TeV for HL-LHC (left panel) and 30ab^{-1} of luminosity at 100 TeV for FCC-hh (right panel).

Finally, we perform a combined three-parameter fit including $C_{u\phi}$, $C_{d\phi}$ and C_ϕ , with the results shown in Figure 6.7. For the same reason as explained before, the bounds on $C_{u\phi}$ and $C_{d\phi}$ are somewhat better than the two-parameter fits of these operators individually with C_ϕ . The HL-LHC and FCC-hh projected bounds on C_ϕ remain nearly the same as those from the corresponding two-parameter fits. In Table 6.5 we also provide the bounds on κ_u , κ_d and κ_λ for comparison.

6.4.3 Interpretation of Shapley values

Finally, we want to demonstrate the interpretability of the machine learning framework we use and discuss the physics that allows for the separation of the signal channels from the background channels. The advantage of using an interpretable multivariate framework is that one can easily understand which of the kinematic variables are important for orchestrating this separation in a manner that significantly improves upon a cut-and-count analysis. As described previously, we use a measure derived from Shapley values, $|S_v|$, to understand the importance of each kinematic variable and, henceforth, understand the differences in kinematic shapes that separate the signal from the background.

To give a feeling of what the values of S_v mean, let us examine a single event. Assuming we have trained the BDT with n kinematic variables, each event with $n \times m$ Shapley values associated with it, m being the number of channels (signal and background channels). For a particular channel, j and kinematic variable, i , S_v can be positive or negative. A positive value implies that it is more likely that the event belongs to channel j according to the value of the kinematic variable i . Conversely, a negative value implies that the event is less likely to belong to channel j given the value of the kinematic variable i . So regardless of whether S_v is positive or negative it helps in the sorting of events

into various channels. Hence, $\overline{|S_v|}$ for a particular variable represents the strength of the variable to distinguish between channels. When summed over all channels this gives an overall picture of how good a discriminant a kinematic variable is for the processes involved. This is what is shown in [Figure 6.8](#) which we will now elaborate upon.

To begin with, we take a look at the $\overline{|S_v|}$ computed for the five channel analysis performed for separating $hh_{\text{tri}}^{\text{ggF}}$ and $hh_{\text{int}}^{\text{ggF}}$ channels from $hh_{\text{box}}^{\text{ggF}}$, $Q\bar{Q}h$ and $b\bar{b}\gamma\gamma$ QCD-QED background. In [Figure 6.8](#) we see the hierarchy plots for HL-LHC (top left panel) and FCC-hh (top right panel) generated from the predictions made by the BDT for this five channel analysis. For both the colliders, H_T is the most important variable that is bringing about separation of the $hh_{\text{tri}}^{\text{ggF}}$ and $hh_{\text{int}}^{\text{ggF}}$ channels from the dominating $b\bar{b}\gamma\gamma$ QCD-QED background. The second most important variable is $m_{\gamma\gamma}$. The importance of $m_{\gamma\gamma}$ accentuates the separation of the background by a greater degree at FCC-hh than at HL-LHC.

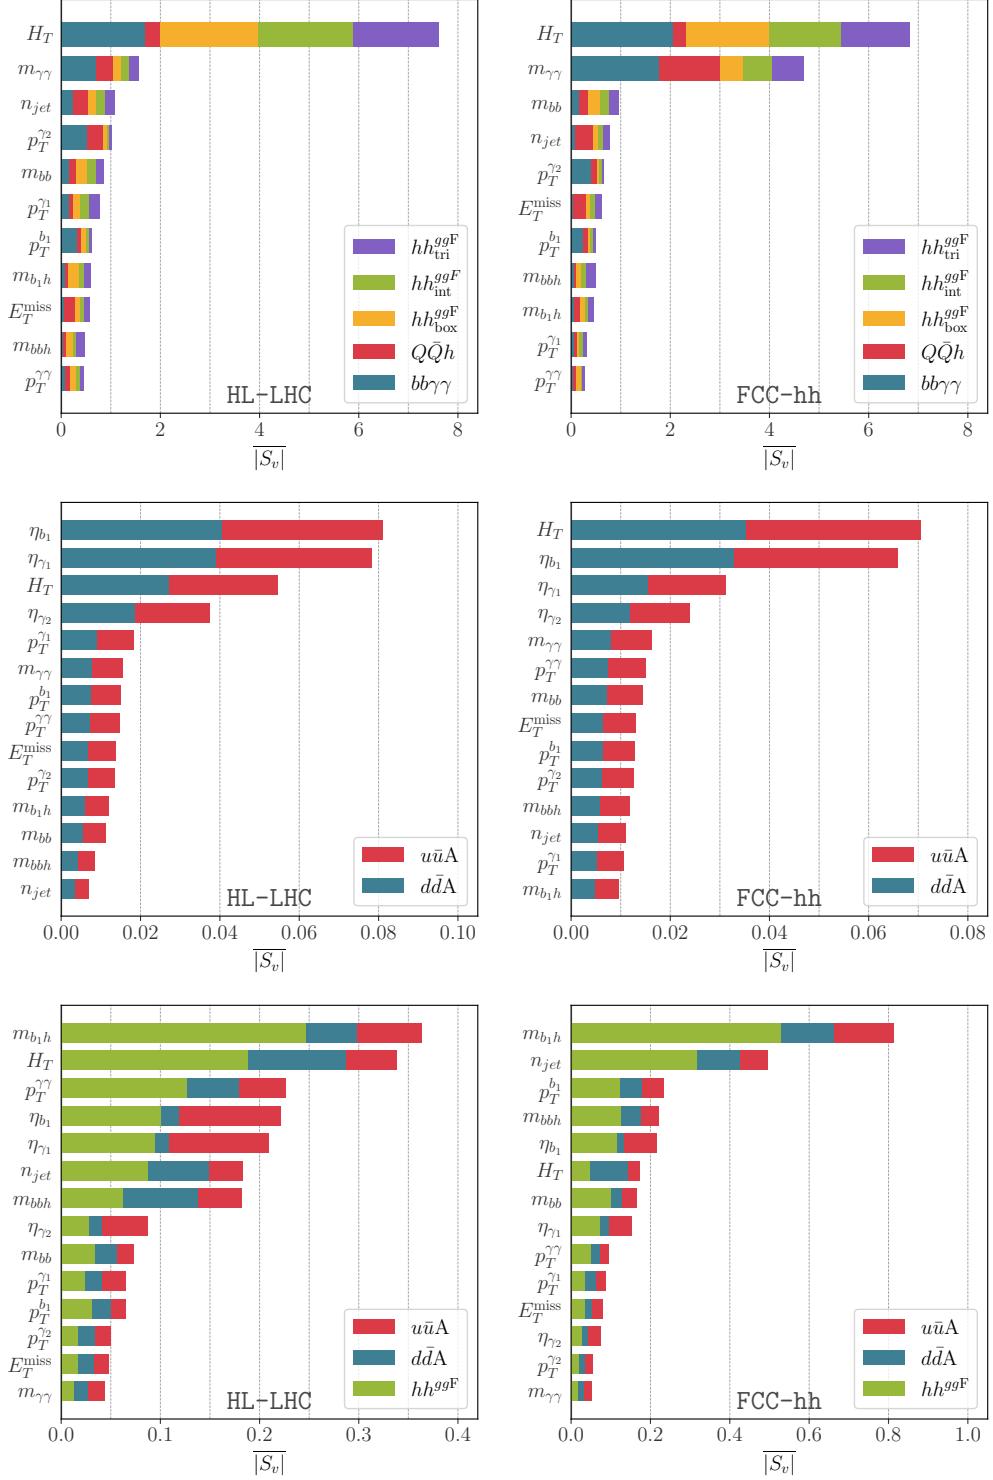

Figure 6.8. Top panels: The hierarchy of variables important for the separation of hh^{ggF}_{tri} from hh^{ggF}_{int} events from hh^{ggF}_{box} , $Q\bar{Q}h$ and $bb\gamma\gamma$ QCD-QED background at HL-LHC (left panel) and FCC-hh (right panel). Middle panels: The hierarchy of variables important for the separation of $u\bar{u}A$ from $d\bar{d}A$ events at HL-LHC (left panel) and FCC-hh (right panel). Lower panels: The hierarchy of variables important for the separation of hh^{ggF} , $u\bar{u}A$ and $d\bar{d}A$ events at HL-LHC (left panel) and FCC-hh (right panel). The higher the value of $|S_v|$ is, the more important the kinematic variable is in separating the different channels.

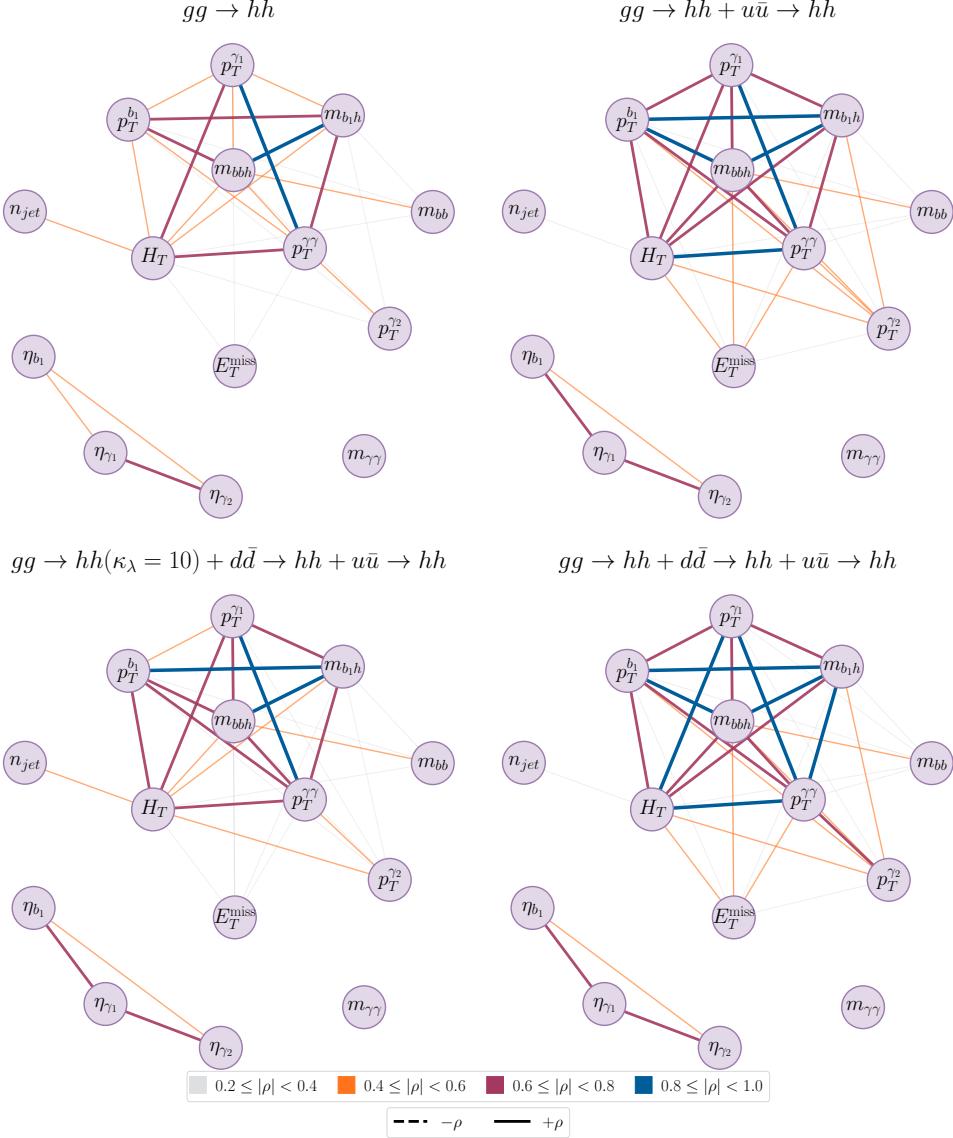

Figure 6.9. Network diagrams visualization of correlations (ρ) amongst the kinematic variables used in the analysis. Top left: Only the gluon-gluon fusion channel. Top right: The ggF channel along with the $u\bar{u}A$ channel with $\kappa_u = 1600$. Bottom right: The $d\bar{d}A$ channel with $\kappa_d = 800$ added to the channels in the top right panel. Bottom left: The same channels as in the bottom right panel but with $\kappa_\lambda = 10$.

For the separation between the two $q\bar{q}A$ channels the story is very different. From the middle panels of Figure 6.8 we see that the separation of $u\bar{u}A$ and $d\bar{d}A$ is truly a multivariate problem. Not surprisingly, the picture is very different for HL-LHC and FCC-hh. The differences between the two channels are driven by the differences in the parton distribution functions (PDF) of the up and down quarks. Since the PDF

for the quarks change significantly from 14 TeV to 100 TeV, the variables that effect the separation of the two channels also change. Thus $|S_v|$ give us a true picture of how distributions of several kinematic variables determine the separation of different channels that are mostly similar. When comparing the abscissa of the top two panels with the middle two panels one will also notice that $|S_v|$ assumes much smaller values in the separation of $u\bar{u}A$ and $d\bar{d}A$. This clearly shows that the two channels are distributed quite identically and are difficult to separate.

Lastly, in the bottom panels of Figure 6.8 we show the variables that are important in separating the $q\bar{q}A$ channels from the ggh Higgs pair production channel. The invariant mass of the leading b -jet and h , $m_{b_1 h}$ is the most important variable at both HL-LHC and FCC-hh. However the hierarchy of variables below $m_{b_1 h}$ are quite different for HL-LHC and FCC-hh. Both H_T and $p_T^{\gamma\gamma}$ are far less important at FCC-hh than at HL-LHC. This displays the clear advantage that machine learning algorithms have over a cut-and-count analysis where separate cut strategies would have to be built for the two colliders leading to two separate analysis that can, instead, be done with the same framework when using machine learning.

The correlation plots in Figure 6.9 show how the linear correlations amongst the variables evolve when different channels are added. The top left panel are events sampled from the ggF distribution. One can already see a clustering in some of the variables related to momenta and invariant mass. The other cluster is of the pseudorapidity of the particles in the final state. This correlation structure evolves when one adds the $u\bar{u}A$ channel when E_T^{miss} gets connected to the upper cluster in the top right panel. The correlation is now stronger between η_{γ_1} and η_{b_1} and several correlations in the upper cluster are much stronger too. The change in the correlations continue as one keeps adding channels as can be seen from the bottom right and bottom left panels. It is the capture of this change in the correlations (and higher-order correlations) that enhances the capabilities of the machine learning algorithms to distinguish between the various channels. While $m_{\gamma\gamma}$ by its shape alone allows for the separation between $b\bar{b}\gamma\gamma$ and the other channels, the correlations between the other kinematic variables aid in the separation of the channels with one or two Higgs in the final state.

6.5 Summary

In this work we walk through an analysis of how kinematic shapes can be used to glean information about the nuances of various production modes with the same final states but deformed differentially by the existence of degrees of freedom beyond the Standard Model. We show that this information can be extracted by using an interpretable machine learning framework which is not only very effective separating these differences in kinematic shapes, but also yields itself to interpretations in terms of physics that is known and well understood. The example we chose is Higgs pair production in the $b\bar{b}\gamma\gamma$ final state. We emphasized that probing Higgs pair production is an important next step for an understanding of the model underlying the fundamental interactions of particles and hence a potential gateway to new physics. We show that even beyond the trilinear

Higgs couplings, the light-quark Yukawa couplings can be probed through this production mode. In fact, the $q\bar{q}A$ channel opens up only in the presence of BSM physics and well motivated models of new dynamics bring about the simultaneous modification of the trilinear Higgs coupling and the light-quark Yukawa couplings. Indeed, we motivated our study by showing that in different frameworks large modifications of the light quark Yukawa couplings can be obtained. Knowing the difficulty of measuring these couplings we propose an interpretable machine learning framework that significantly outperforms traditional cut-based analyses.

As opposed to using black-box models, the interpretable framework allows us to gain physics insights into how signal and background separation can be brought into effect, pointing to kinematic variables like H_T and $m_{\gamma\gamma}$ as being important variables that instrument this separation. As a result we find enhanced sensitivities to C_ϕ or κ_λ that quantify the modification to the Higgs trilinear coupling. Furthermore, we see that the measurement of the light-quark Yukawa couplings is aided by using the methods we advocate bringing about far greater sensitivities than would be possible with a cut-based analysis at the HL-LHC and the FCC-hh. The advantage of using an interpretable framework using Shapley values is that it provides added confidence to the robustness of the multivariate analyses that we perform using simulated data.

The salient results of this work are:

- The modification of the Higgs trilinear coupling can be measured at $\mathcal{O}(1)$ precision at the HL-LHC and at $\mathcal{O}(1\%)$ precision at the FCC-hh.
- The rescaling of the light-quark Yukawa couplings, κ_u and κ_d , can be measured to $\mathcal{O}(100)$ at the HL-LHC and $\mathcal{O}(10)$ at FCC-hh. This translates to $C_{u\phi}$ and $C_{d\phi}$ constrained at $\mathcal{O}(10\%)$ at the HL-LHC and $\mathcal{O}(1\%)$ at FCC-hh.
- The measurement of C_ϕ , or κ_λ , is significantly diluted once the light-quark Yukawa couplings are allowed to vary. Hence, in a joint fit, the bounds on C_ϕ are much weaker.
- There are theoretical models that motivate the simultaneous modification of the trilinear Higgs coupling and the light-quark Yukawa couplings. Hence, the dilution of the bounds on C_ϕ due to the presence of NP in the light-quark Yukawa sector should be taken into consideration in future phenomenological extraction of C_ϕ .
- The bounds obtained with the interpretable machine learning framework that we use not only outperforms cut-based analyses by far, but also allows for physics insights into kinematic distributions of the various channels that helps distinguish them in an experiment.

In conclusion, we stress that the interplay between the Yukawa sector and the Higgs trilinear coupling is non-trivial and requires careful consideration. Future experiments at the HL-LHC and FCC-hh will bring significant improvements in the sensitivities to C_ϕ , $C_{u\phi}$ and $C_{d\phi}$ through the Higgs pair production channel. In particular, the bounds on the light-quark Yukawa couplings from Higgs pair production can possibly be the most stringent bounds amongst all other experimental probes of the light quark Yukawa couplings.

6.6 Discussion of theoretical and systematic uncertainties

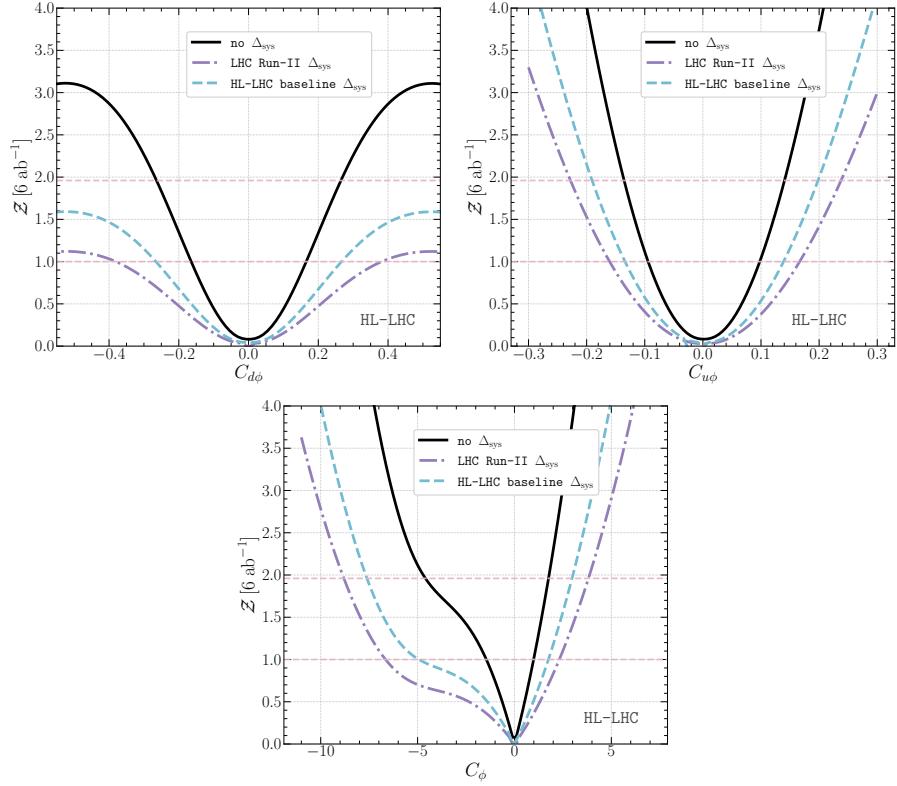

Figure 6.10. The significance Z from a single parameter fit for $C_{d\phi}$ (upper left panel) , $C_{u\phi}$ (upper right panel) and C_ϕ (lower center panel) for the HL-LHC with no systematic uncertainties (black) and two ansätze for systematic uncertainties. The first is the current Run-II 8.2% in violet and the HL-LHC baseline 5.3% estimated by ATLAS in blue, including theoretical uncertainties without top mass renormalisation scheme.

In this section we present an estimate of the systematic uncertainties that can affect the measurements discussed in this work at the HL-LHC. We do not present these estimates for the FCC-hh for lack of sufficient information or the ability to project such uncertainties far into the future. We use two scenarios for systematic uncertainties: the first is a 8.2% uncertainty which corresponds to the current systematic uncertainty that ATLAS has reported for their Run-II search for Higgs pair production [280]. The second scenario is the ATLAS HL-LHC baseline systematic uncertainty of 5.3% reported in [202]. For LHC run-II, statistical uncertainties remain the dominant part of the uncertainty budget for di-Higgs analysis. Regarding the systematic uncertainties, experimental sources remain the dominant part in comparison to the theoretical ones. The story flips for the HL-LHC where the main source of uncertainties is expected to be coming from theoretical uncertainties. The current theoretical uncertainty estimate of the SM gluon fusion process at NNLO is $^{+6\%}_{-23\%}$ for $\sqrt{s} = 14$ TeV and $^{+4\%}_{-21\%}$ for

$\sqrt{s} = 100\text{TeV}$ [238]. The largest part of the uncertainty stems from the uncertainty due to the renormalization scheme choice of the top quark mass. This uncertainty can, for the moment, only be estimated at NLO since no full mass dependent results at NNLO are available. Moreover, the top quark mass renormalization scheme uncertainty is not included in the estimated HL-LHC (nor LHC Run II) uncertainties schemes that we have considered.

In Figure 6.10 we show the significance \mathcal{Z} for the three Wilson coefficient, C_ϕ , $C_{u\phi}$ and $C_{d\phi}$, at the HL-LHC from single parameter fits with no systematic uncertainties (black), LHC Run-II (violet) and HL-LHC baseline (blue) systematic uncertainties ansatze. We observe that for the current Run-II ansatz, the bounds for all three Wilson coefficients is diluted by 100% or more. As for the HL-LHC baseline, the bounds are diluted by $\sim 70\%$. However, it should be noted, that both systematic uncertainties scenarios are rather conservative. It is likely that the HL-LHC detector upgrade and new theoretical developments in higher-order corrections to di-Higgs cross-section will reduce the systematic uncertainties from the baseline.

6.7 Light-quark Yukawa and Self Coupling at Future Lepton Colliders

Future high energy lepton colliders [281–283] offer further alternative and clean signals for measurement of Higgs properties. For example, Higgs decays to “un-tagged” light jets including u, d, s quarks can be further disentangled from $H \rightarrow gg$ using event shape analysis [284] and can reach a sensitivity of $\kappa_d \approx 90$ and $\kappa_u \approx 192$ at 250 GeV with 5ab^{-1} data compared with a sensitivity of $\kappa_d \approx 470$ and $\kappa_u \approx 900$ at the 6ab^{-1} HL-LHC [285, 286].

The sensitivity to Higgs self-coupling comes indirectly for center of mass energy below 250 GeV from the precision measurement of the Zh production channel ($\delta\kappa_\lambda$ (1σ) 0.4 at 250 GeV), and at 500 GeV directly from the Zhh channel ($\delta\kappa_\lambda$ (1σ) 0.27 at 500 GeV), and from vector boson fusion like production to $hh\nu\nu$ when 1 TeV or higher energy scales are available ($\delta\kappa_\lambda$ (1σ) 10% at 1 TeV). The prospective sensitivity depends on the collider setup, mainly the integrated luminosity and polarization of initial lepton beams. Given the updated prospects of future machine designs [287], we list a short summary in Table 6.6 of the expected sensitivities on the individual parameters in the κ framework. These numbers are all assuming one-parameter fits in κ or (translated from) SMEFT framework. No simultaneous fit including both κ_q and κ_λ (or using the corresponding SMEFT operators) have been performed yet.

Collider	$ \kappa_u $	$ \kappa_d $	$\delta\kappa_\lambda$ (1σ)
240 GeV 5ab^{-1} (CECP/FCC)	192 [284]	90 [284]	100% (Indirect[168])
350 GeV 1.5 ab^{-1} (FCCee)	310[287]	140[287]	40% (Indirect[168])
500 GeV 4 ab^{-1} (ILC)	330[287]	160[287]	27% [282]
1 TeV 8 ab^{-1} (ILC)	—	—	10% [287]
3 TeV 1 ab^{-1} (CLIC)	430[287]	200[287]	10% [287]
10 TeV 10 ab^{-1} (Muon)	—	—	3% [287]

Table 6.6. Prospective light-quark Yukawa and Higgs self-coupling sensitivities at future lepton colliders. The light-quark Yukawa bounds are 95% CL, while the self-coupling bounds are 1σ or 68% CL sensitivity reach.
